EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The accounts of this Company to December 31st last show, subject to audit, a balance of profit of £157,093. 14s. 7d., after payment of three interim dividends. The Directors now propose to distribute on the 19th prox. the usual dividend of 2s. 6d. per share, making a total dividend of 5 per cent. for the year 1892, together with a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the year. The balance of £75,843. 14s. 7d. has been carried to the reserve fund. The share register will be closed from the 12th to 19th April, both days inclusive.——The Company also give notice that the tenth drawing for payment of the Five per Cent. Australian Government Subsidy Debentures (353 in number) will take place on the 6th prox., at the offices of the Company, Winchester House, Old Broad-street, E.C., at 11:30 a.m.

EDISON ELECTRIC ILLUMINATING COMPANY (U.S.A.).—This Company will shortly issue $3,500,000 additional stock, nearly the whole of which will be utilised in retiring its outstanding bonds, $250,000 of the amount being used for the development of the Company's business.

EPSTEIN ELECTRIC ACCUMULATOR COMPANY (LIMITED).—It is announced that Mr. Frederick R. Bluett has been appointed Secretary to the Company, and that the offices are now at 213, Gresham House, Old Broad-street, E.C.

FOWLER, LANCASTER, AND CO. (LIMITED).—A petition was presented on the 9th inst. by the Electrical Company (Limited) for the compulsory winding up of this Company (now in voluntary liquidation), and is down for hearing at the Royal Courts of Justice, London, on April 11th.

THE LONDON AND SOUTH-WESTERN RAILWAY COMPANY.—A considerable rise has recently taken place in the stock of this Company doubtless owing to the passing of the Bill for constructing and erecting an underground railway from Waterloo to the Mansion House, thus effecting access by the South-Western Company into the City.

REDRUTH ELECTRIC SUPPLY COMPANY (LIMITED).—The prospectus of this Company will be found in our advertisement columns. The Company is formed with a capital of £10,000, in 2,000 shares of £5—payable £1 on application, £1 on allotment, £1 three months after allotment, and the balance as required (after three months' notice). The Directors include Mr. Edward Tangye, engineer, and Mr. Joseph Pryor, mining engineer. The engineer to the Company is Mr. E. W. Tangye, who was lately with the Brush Electrical Engineering Company, London. The secretary (*pro tem.*) is Mr. C. Tweedy, and the offices are at Green-lane, Redruth, Cornwall. The prospectus states that the Company is formed to supply electric current to the town of Redruth, and the Directors give their services free until a dividend of 5 per cent. is declared. There is no promotion money, and the Company have the offer of a long lease of a site well adapted for the object in view at the yearly rental of £15, including the right to water, of which there is an excellent supply. The Local Board has consented to the establishment of the Company, which proposes to supply the district with current at about 4½d. per unit (=gas at 3s. 6d. per thousand). The Company has already promises of 750 16-c.p. lamps at £1 per annum per lamp. It is estimated that £5,000 capital will purchase the necessary plant for the maximum load of 1,000 16-c.p. lamps, and that the total capital of the Company (£10,000) will amply suffice to provide for 3,000 lamps. The estimated working expenses have been calculated at about £450 per annum up to about 1,500 lamps. The capital expenditure is considerably reduced from the fact that the mains go for about 500 yards in a perfectly straight course, and the Directors anticipate a fair day load from the use of motors and accumulator charging. It is proposed to use a low-pressure system.

Hosted by Google

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended March 17, 1893, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,255.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts for the two weeks ended March 15th were £3,017, as compared with £2,895 for the corresponding period of last year. November receipts, estimated at £4,477, realized £4,511.

Sole Agents for the "NEVILE" AUTOMATIC ACCUMULATOR SWITCH.

This Switch balances the voltage of the cells against that of the dynamo, making and breaking the circuit when the one exceeds the other by more than 1 per cent.

They have been in use for many years, and should be fixed in every accumulator installation as a safeguard against the breaking of the belt or any other accident.

AS THE ACTION IS ABSOLUTELY RELIABLE THE NECESSITY FOR CONSTANT ATTENDANCE WHILE THE CELLS ARE BEING CHARGED IS OBVIATED BY THE USE OF THIS APPARATUS.

TO CAPITALISTS, GENERAL AND ELECTRICAL ENGINEERS, AND OTHERS,

TENDERS are invited for the STOCK, PLANT, MACHINERY and EFFECTS of a going concern in the Electrical and General Engineering trade, together with its PATENTS, LICENCES and GOODWILL, and the trade name of the same. The business has been established in the West Riding of Yorkshire for over fifteen years.

The General Engineering Shops are fitted with the most modern tools for turning out high-class work.

The Dynamo, Electric Light and Construction Departments, are similarly laid out with every modern appliance.

The Telegraph, Telephone and Railway Signalling Departments are fitted up with the most modern automatic and other machinery for producing work in large quantities at a minimum cost.

Particulars and all information and permission to view may be obtained at the offices of Messrs. LAKEMAN and OLIVER, Prudential Buildings, Park Row, Leeds.

Tenders must be sent in to Messrs. Lakeman and Oliver not later than WEDNESDAY, the 12th April, 1893.

Nine Words to the Line.

SITUATIONS VACANT AND WANTED, &c.

DRAUGHTSMAN.—Knowledge of Electrical and General Engineers' work.—Apply, by letter, to T. O. BELSHAW, 53, Victoria-street, London, S.W.

WANTED, a capable ELECTRICAL ENGINEER, with fair connection, and about £2,000 capital, to join a well-established business in London. Principals only.—Apply, "A. L.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

WANTED first-class VACUA HAND, accustomed to electrical work and capable of carrying out a series of accurate measurements to ascertain the relative conductivities and the illuminating powers of various definitely determined degrees of vacua with different gases.—Apply personally, after April 5, at 34, New Tothill-street, Westminster, S.W.

ADVERTISER, large experience in Australian Railway Electrical Instruments, Tyers tablet, Preece's 3-wire, staff, telephones, registers, wishes to obtain POSITION on English Railway.—"TABLET," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

J. WEEKS AND CO., Horticultural Builders to Her Majesty, H.R.H. the Prince of Wales, H.M. Government, Admiralty Dept., War Dept., Royal Hort. Soc., Royal Botanic Soc., Parks and Public Buildings. Patentees of the Duplex Upright Tubular Boilers. King's-road, Chelsea, S.W.

Miscellaneous Advertisements, Plant Wanted and for Sale, &c., &c., continued on next page.

THE ELECTRICAL and GENERAL ENGINEERING COLLEGE and SCHOOL OF SCIENCE.

PENYWERN HOUSE

2, Penywern Road, EARL'S COURT, S.W.

Principal: G. W. de TUNZELMANN, B.Sc., M.I.E.E.

The Complete Courses qualify Students for entry into Electrical and other Engineering Work.

The First Year's Course is arranged to qualify for entry into Cooper's Hill, the Central Institution, and the Royal School of Mines.

Extensive Laboratories, Dynamo Room, &c.

Students are regularly sent to the College by leading Engineers and Scientific Authorities, whose names are given in the Prospectus.

JUST PUBLISHED. WAISTCOAT-POCKET SIZE.

With Illustrations, 128 pages, 64mo, roan, gilt edges, 1s.; 1s. 1d. post free.

ELECTRICAL TABLES AND MEMORANDA.

By SILVANUS P. THOMPSON, D.Sc., B.A., F.R.S., and EUSTACE THOMAS.

LONDON: E. & F. N. SPON, 125, STRAND.

NEW YORK: 12, CORTLANDT STREET.

WANTED, and FOR SALE.

WANTED ARC-LIGHTING PLANT for about 30 lights, must be modern type and equal new.—Apply "P. F.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

WANTED good second-hand GAS ENGINE and DYNAMO COMBINED, together with Accumulators for about 30 16-c.p. Incandescent Lamps. State lowest price and where same can be seen.—Apply by letter, THE ELECTRIC WIRING AND FITTINGS Co. (Limited), 2, Princes-street, Great George-street, Westminster, S.W.

J. WEEKS AND CO., King's-road, Chelsea, S.W., supply all kinds of Boilers, their improved and other Valves, tested Hot-water Pipes, Castings, Connections and Fittings at lowest retail prices.

MESSRS. DEBENHAM, TEWSON, FARMER, and BRIDGEWATER have a large selection of SHOWROOMS, OFFICES, WAREHOUSES, and FACTORIES suitable for ELECTRICAL ENGINEERS.

Their Monthly List is now ready, and may be obtained at their Offices, 80, CHEAPSIDE, E.C., or will be forwarded free by post

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK FOR 1893.

NOW READY, price 7s. 6d., post free 8s. 3d., abroad 8s. 10d.

More than 1,000 pages of RELIABLE Matter. The only COMPLETE Electrical Directory.

"THE ELECTRICIAN" PRINTING AND PUBLISHING CO., Ltd., Salisbury-court, Fleet-street, London, E.C.

"THE PATENTEES' HANDBOOK,"

BY

J. G. LORRAIN, M.Inst.E.E., M.Inst.M.E.,

CHARTERED PATENT AGENT,

Gives full information and advice to intending Patentees. Sent post free on application to Mr. J. G. LORRAIN, Norfolk House, Norfolk-street, Strand, London, W.C.

Messrs. WILLIAMS and NORGATE, Importers of Foreign Books, have weekly parcels from the Continent with all the new Scientific Books.

(*Foreign Prices*).

1886	... „	3,257,609	... „	5,672,041
1891	... „	**4,546,577**	... „	**7,894,357**

INCREASE OF FUNDS IN TEN YEARS, £3,221,058.

EXTRACT FROM AUDITORS' REPORT.

"We have examined all the Securities held here . . . . and have found them correct and in order, and we further certify that the present aggregate Market Value thereof is in excess of the amounts in the Balance Sheets."

JOHN H. MCLAREN, Manager.
DIGBY JOHNSON, Sub-Manager.
CHARLES ALCOCK, Secretary.
JOHN H. CROFT, Secretary in London.

UNIVERSITY COLLEGE, BRISTOL.

ENGINEERING DEPARTMENT.
PROFESSOR RYAN, M.A., LL.M., D.Sc.

COURSES on CIVIL, MINING, and ELECTRICAL ENGINEERING will be held during the Third Term, commencing April 25th. The Course on Electrical Engineering will comprise Electric Lighting, Dynamo-Electric Machinery, and Transmission of Power. Professor LLOYD MORGAN will conduct Geological Excursions in the Field, and Messrs. GARRATT and WALKER will give Outdoor Demonstrations in Surveying. Special Series of Lectures will be given on Bridge Construction and Electro-Technics.

For further information apply to

JAMES RAFTER, Secretary.

NOW READY.

"HOUSE LIGHTING BY ELECTRICITY,"

POPULARLY EXPLAINED.

By ANGELO FAHIE, M.I.E.E.

Large 8vo. Illustrated. Paper Cover, 1s. Cloth and gilt, 2s.

LONDON: E. and F. N. SPON. DUBLIN: J. FALCONER. NEW YORK: SPON and CHAMBERLAIN.

To be had of all Booksellers.

"PATENTS: SOME POPULAR DELUSIONS.'

W. Lloyd Wise, Esq., J.P., C.C., Fellow of the Chartered Institute of Patent Agents, London. See CALVERT'S MECHANICS' ALMANAC for 1893. Price 4d.

LONDON: JOHN HEYWOOD, 2, Amen-corner.

THE "ELECTRICIAN" SERIES.

The following Standard Electrical Works are sent post free to any address at the prices quoted :—

IN TWO VOLUMES.

THE ALTERNATE CURRENT TRANSFORMER IN

THEORY AND PRACTICE. By J. A. FLEMING, M.A., D.Sc. (Lond.), Professor of Electrical Engineering in University College, London, &c., &c.

Vol. I., *500 pages, 157 illustrations. Third Issue, price 7s. 6d., post free (U.K.); abroad, 8s. 2d., post free.*

Synopsis of Contents.—Chapter I. Introductory.—Chapter II. Electro-Magnetic Induction.—Chapter III. The Theory of Simple Periodic Currents.—Chapter IV. Mutual and Self Induction.—Chapter V. Dynamical Theory of Current Induction.

Vol. II., *over 600 pages, and more than 300 illustrations. Price 12s. 6d., post free.*

Synopsis of Contents.—Chapter I. The Historical Development of the Induction Coil and Transformer.—Chapter II. Distribution of Electrical Energy by Transformers.—Chapter III. Alternate-Current Electric Stations.—Chapter IV. The Construction and Action of Transformers.—Chapter V. Further Practical Applications of Transformers.

370 pages, 159 illustrations, price 10s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS.

By J. A. EWING, M.A., B.Sc., &c.

After an introductory chapter, which attempts to explain the fundamental ideas and the terminology, an account is given of the methods which are usually employed to measure the magnetic quality of metals. Examples are then quoted showing the results of such measurements for various specimens of iron, steel, nickel, and cobalt. A chapter on Magnetic Hysteresis follows, and then the distinctive features of induction by very weak and by very strong magnetic forces are separately described, with further description of experimental methods, and with additional numerical results. The influence of Temperature and the influence of Stress are next discussed. The conception of the Magnetic Circuit is then explained, and some account is given of experiments which are best elucidated by making use of this essentially modern method of treatment. The book concludes with a chapter on the Molecular Theory of Magnetic Induction; and the opportunity is taken to refer to a number of miscellaneous experimental facts, on which the molecular theory has an evident bearing.

The same book in German, price 8s. 6d., post free.

In Two Volumes—Price: stout paper covers, 2s., post free 2s. 2d. each; strong cloth, 2s. 6d., post free 2s. 9d. each. Single Primers, 3d., post free 3½d.

"THE ELECTRICIAN" PRIMERS. Fully illustrated.

A Series of Helpful Primers on Electrical Subjects.

TABLE OF CONTENTS:

Volume I.—THEORY.

Primer No.		Primer No.	
1.	The Effects of an Electric Current.	11.	The Galvanometer.
2.	Conductors and Insulators.	12.	Electrical Measuring Instruments.
3.	Ohm's Law.	13.	The Wheatstone Bridge.
4.	Primary Batteries.	14.	The Electrometer.
5.	Arrangements of Batteries.	15.	The Induction Coil.
6.	Electrolysis.	16.	Alternating Currents.
7.	Secondary Batteries.	17.	The Leyden Jar.
8.	Lines of Force.	18.	Influence Machines.
9.	Magnets.	19.	Lightning Protectors.
10.	Electrical Units.	20.	Thermopiles.

Volume II.—PRACTICE.

Primer No.		Primer No.	
21.	The Electric Telegraph.	30.	The Incandescent Lamp.
22.	Automatic and Duplex Telegraphy.	31.	Underground Mains.
23.	The Laying and Repair of Submarine Cables.	32.	Electric Meters.
		33.	Electric Light Safety Devices.
24.	Testing Submarine Cables.	34.	Systems of Electric Distribution.
25.	The Telephone.	35.	Electric Transmission of Energy.
26.	Dynamos.	36.	Electric Traction.
27.	Motors.	37.	Electro-Deposition.
28.	Transformers.	38.	Electric Welding.
29.	The Arc Lamp.		

The object of "The Electrician" Primers is to briefly describe in simple and correct language the present state of electrical knowledge. Each Primer is short and complete in itself, and is devoted to the elucidation of some special point or the description of some special application. Theoretical discussion is as far as possible avoided, the principal facts being stated and made clear by reference to the uses to which they have been put. Both volumes are suited to readers having little previous acquaintance with the subject. The matter is brought up to date, and the illustrations refer to instruments and machinery in actual use at the present time.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 776.—Vol. XXX. FRIDAY, MARCH 31, 1893. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The last meeting of the Institution of Electrical Engineers was very thinly attended. Photometry does not pay; there is no money in earth currents, and, at present, even less in electrical tanning. The first of the three Papers would have received more attention if presented to the Physical Society, the second to the Royal Meteorological Society, and the last to the Society of Chemical Industry. The Institution of Electrical Engineers is, in fact, thoroughly commercial at heart, though its best work is scientific. The remarks of the President in closing the meeting are well worthy of attention. Electrical engineering consists of something more than dynamo-building and transformer-testing.

Papers on the common run of subjects are easily discussed; practical men have their own ideas and trot them out, and whether they happen to support the views of the Paper or no, does not matter much. Still less are the theoretical men at a loss. But when something new is brought forward, or when a somewhat obscure or complicated matter is introduced, useful discussion is impossible unless the Paper has been previously circulated among those who may be expected to take part in the debate. The Institution of Electrical Engineers seems likely to achieve for itself the unenviable distinction of being the only scientific society that does not take the trouble of issuing advance proofs of its Papers. The rule laid down by the President that the discussions shall be confined to the Paper, and shall not circuitously regurgitate upon itself, is an admirable one, but when, for example, a photometer involving several novel points and somewhat complicated mechanism is exhibited and illustrated by photographs on a screen, it is not surprising if the discussion is diverted towards standard candles and other matters. A distinct drawback to the illustration of Papers by the lantern is that the diagrams are not before the audience during the whole meeting. If they cannot follow the author's delivery they can at least study the diagrams of the Paper which they hope some day to peruse.

The presentation of Mr. Falkenstein's Paper was doubly unfortunate. Not only would it be quite impossible to discuss such a communication without a careful study of the Paper, but it was taken at a late hour, read in disconnected fragments at a scramble, and discussion, at all events for that evening, was out of the question. A more discouraging reception could not well have been given to this, the first work of a junior member of the Institution, and since other societies are ready to do justice to such researches, it is not surprising that the Institution of Electrical Engineers by no means enjoys the monopoly of electrical Papers. Quite apart from its application to tanning, Mr. Falkenstein's Paper, so far as any estimate could be formed of it, promises to be a valuable contribution to the difficult and hitherto even un-named branch of electro-chemistry which deals with the transference of matter, and of which the migration of ions and electrolysis is but a sub-division. One well-known chemist, at all events, attended the meeting in expectation of hearing the Paper and of taking part in the discussion, and was not a little disappointed in failing to obtain a copy and in finding the discussion snuffed out.

A rather remarkable instance of triple invention is afforded by the proposal of M. Blondel to use an arc lamp and a system of perforated screens for providing a unit of light, and the identical proposal of Mr. Swinburne, and the suggestion of Prof. S. P. Thompson. The first was briefly described by our Paris Correspondent on page 539 of our issue for March 10th. The second was published in *The Electrician*, Vol. XXIX., page 65, in our report of the discussion which took place at the Institution of Electrical Engineers on April 28, 1892; the third, on p. 66 of the same volume, being a report of the adjourned discussion, when a communication was read from Prof. S. P. Thompson, who was then on the Continent. Prof. Thompson confined himself to throwing out a suggestion. Mr. Swinburne described exactly the arrangement of screens used by M. Blondel, and the author of the Paper under discussion threw cold water on both propositions, since the dusky appearance of the core of a cored carbon led him to expect a difference in the emissivity of different kinds of carbon. This difference M. Blondel finds to be negligible, and thus the value of the "arc standard of light," as he calls it, is established. At present no quantitative results have been published.

The new Déri alternate-current motor described in our columns this week, is interesting for two or three reasons. It is of the open-circuit type, and the torque at starting can be made considerable. It will run at various speeds according to the position of the brushes. It is said to be efficient and to run without sparking; but as only a small portion of the armature-coils is in action at any given moment, the

Hosted by Google

power of the armature must be small, considering the weight of copper on it.

In a communication to the Académie des Sciences, M. d'Arsonval adheres to the widespread idea that the physiological effects of high-frequency currents is small. He refers to Mr. Campbell Swinton's explanation, recorded in *The Electrician*, December 9, 1892, p. 145, but evidently fails to grasp it. The fault is perhaps ours, since we had the privilege of publishing it in a Note. M. d'Arsonval cites an experiment to show that Mr. Swinton's explanation is erroneous. He brought a fine platinum wire to redness with a high-frequency current; he plunged it into a vessel of petroleum, and noted the rise of temperature which corresponded to the passage of the current for, say, five minutes. He then raised the wire to the same temperature by means of a continuous current, and observed that the heating of the petroleum was the same in the two cases. He adds that Mr. Campbell Swinton admits this explanation. We hope, however, that we here misunderstand M. d'Arsonval and that Mr. Swinton has not recanted, for his theory seems thoroughly sound, and we venture to add that M. d'Arsonval's experiment seems quite illusory. According to Mr. Swinton's explanation only the skin of the wire or of the lamp filament is taking part in conveying the high-frequency current. The C^2R effect depends then not on the natural ohmic resistance of the wire, but on the resistance of a cylindrical shell of unknown thickness, the interior core taking little or no part in the matter. We have already proposed that if the fall of volts could be measured, the current could be estimated from the watts, and M. d'Arsonval's calorimeter would doubtless be better than the glow lamp and photometer which we suggested. Mr. Swinton has attempted to do this with a Kelvin electrostatic voltmeter, but the instrument became filled with brush discharges in all directions, and indicated only some 500 volts or so. It is doubtful whether the filling of the whole case of the instrument with some limpid dielectric would enable a true measurement to be made. Spark length measurements are of no use here; what is wanted is the true average value of the volts.

The Westinghouse Company has acted with commendable generosity and policy in limiting its levies under the Hopkinson Three-Wire Patent to £2. 10. per annum per ton of copper laid. We have always held that the practice of keeping "master" patents in a state of quiescence, and allowing an infringing industry to grow up, either in ignorance of the very existence of the patent or in belief that it will never be made use of, although legally correct and perhaps tactically admirable is one which it is impossible to countenance. If it were possible to discover a remedy not worse than the disease, the law ought to be altered so as to stop the game. The Hopkinson patent was ten years old before its rights were enforced, and although the patentee and his assigns between them could no doubt give a very good explanation of this long delay, the fact remains, and the feeling of irritation it gives rise to exists. Under the circumstances, therefore, the Westinghouse Company has done well not to introduce the oppressive tactics of the General Electric Company of America into the United Kingdom. The Brighton Town Council, as we have already announced, stoutly repudiates the gentle insinuation that it is using the three-wire system, but the Town Councils of Dundee and Hull have wisely deemed discretion the cheaper part of valour, and have consented to be taxed by the Westinghouse Company. At Hull 22 tons of copper have been laid down, so that the Town Council will only have to pay £55 a year until July, 1896.

Telephony seems to be one of those few industries in which a reduction cannot be made "on taking a quantity," and it is said that, after a certain number of subscribers are connected, the system becomes so unwieldy that further increase is likely to diminish rather than to increase the profits. But this seems to be largely due to the necessary expenditure on new lines, wayleaves and instruments. There is, however, a very considerable *clientèle* which the National Company has hitherto neglected to cultivate, but which could be made to yield a good return with little or no capital outlay on the part of the Company, and without the smallest addition to the switchboards in the exchanges. In every direction in business London huge office warrens are to be seen, tenanted for the most part by business men to whom a telephone at a reasonable price would be a decided boon. Many of these warrens possess a common telephone. What could be easier than for the National Company to arrange with the proprietors for a simple plug switchboard to be looked after by the hall-porter, and for the running of wires from it to the rooms of those who are prepared to pay, say £5 a year, for the *n*th share of the common Exchange wire? We understand that £10 or £15 a year has been demanded for such a connection, but have not heard that it has ever been accepted. If the National Company wish to spend no more capital, the tenants or the landlords of the offices would, we think, run the wires and provide the instruments. There may, however, be working difficulties which are not apparent.

From a letter recently received by the Edinburgh Town Council it would appear that something in the nature of an Electric Traction Association is in process of formation. This is as it should be. As a matter of fact, however, it seems to us that, since so many local authorities have a more or less direct interest in tramways, an effective way of checking the clause-inserting career of the National Telephone Company would be to induce the Municipal Corporations Association to take action. If we recollect aright, something of the kind was attempted last year in the case of the Blackpool Improvements Bill, though with what result we cannot say. The Salford Town Council, to whose action in withdrawing the tramway clauses of their Improvements Bill we alluded last week, by so doing certainly succeeded in temporarily checkmating the National Company. On the other hand, the attempt of the National Company to force upon the Salford Town Council a retrospective protective clause covering the whole tramway system of that town, on the occasion of powers being demanded to double a single section, was an object-lesson in this Company's attitude rendering it advisable for the Municipal Corporations Association to have fought the

Hosted by Google

issue out to the bitter end. While desirous that under ordinary circumstances every facility should be accorded to the National Company in the matter of wayleaves, we would point out that so far as municipal authorities are concerned, they can bring considerable pressure to bear upon their adversaries by merely refusing to assist them in their efforts to obtain wayleaves until a satisfactory *modus vivendi* has been arrived at.

We wonder how many of the 1,700 or 1,800 members and associates of the Institution of Electrical Engineers ever perform a work of supererogation by analysing the balance-sheet which they pass every year with all due formality. A remark let fall at the last meeting induced us to see if we could extract a broad fact or two from the 1892 accounts, recently placed in the hands of all those connected with the Institution. The net outcome of our examination is that the Institution has invested in various Government securities, and for various purposes, a sum of close on £5,000, that its annual receipts from all sources amount to nearly £3,600, and its annual ordinary expenditure to £2,300, being nearly £300 more in 1892 than in 1891. The net cost of the *Journal* last year, including reporting, printing, postage, and advertising, was about £750. Under the items of extraordinary expenditure we note £118. 10s. in connection with the compilation and printing of the Index to Vols. XI.-XX., of the *Journal*. The financial position of the Institution, like that of most other electrical concerns, is modest, and, unlike that of some, it is sound.

Sir John Kennaway's Committee were apparently in a rejecting mood last week. On Monday the Clapham Junction and Paddington Railway received its quietus, the professorial ferule and not "a bare bodkin" being the means of its despatch. On Friday the Kilburn, Edgware-road and Victoria line fell before the heterogeneous forces of the London County Council, a City alderman and a couple of dukes. The opposition was not only unusually powerful, but, what is rather more uncommon, it had an unusually strong case. A somewhat wanton interference with the "amenities" of valuable property, public and private, was threatened and the Committee were not satisfied that the line when authorised would not be converted into a means of filling the pockets of its promoters, with no corresponding benefit to the public. With the Central London Railway still incubating in the City and four new lines authorised, it is not altogether desirable from the point of view of broad public policy that any more lines should be sanctioned in a hurry. The Kilburn, Edgware-road and Victoria Railway would have proved, without a doubt, a boon to a large and rapidly-growing suburban population, and when the promoters of the lines already authorised have got to work —engineering work, we mean—Select Committees will not, we feel sure, unnecessarily delay further developments of our metropolitan electric railway network.

As is customary, the witnesses of the threatened property-owners rather overdid their case, and one gallant gentleman solemnly assured the Committee that he had been told by "those who possessed technical knowledge" that "the electrical currents of the railway would seriously affect the storage-power of the accumulators placed in the cellars of Nos. 4 and 5, Grosvenor-place." If the names of these possessors of such valuable technical knowledge were known, we are afraid their earning power as electrical experts would be seriously affected.

Canal Lighting.—The Corinth Canal is to be lighted at night by arc lamps placed on the banks.

Académie des Sciences.—Sir Henry Roscoe has been elected "Correspondant pour la Section de Chimie," and Sir Joseph Lister, "Associé Étranger."

Cable Interruptions—

Cables.	Date of Interruption.
Gibraltar-Tangier	February 18th
Para-Maranham	March 20th.

The London County Council (General Powers) Bill.—Sir W. Hart Dyke has been appointed Chairman of the Select Committee of the House of Commons on this Bill, and the Committee will sit to take evidence on April 13th.

Brighton.—The report of Mr. I. B. Walker and Major Cardew, Board of Trade Inspectors, with regard to the opposition of the Town Council to the granting of a Provisional Order to the Brighton Electric Light Company, has been published. It is unfavourable to the Company. Whilst of opinion that the Company has some claim upon the consideration of the Corporation, the Inspectors cannot recommend the Board of Trade to dispense with the consent of the Brighton Corporation.

The Liverpool Overhead Railway.—At the last weekly meeting of the Mersey Docks and Harbour Board the Works Committee recommended the Board to allow the Liverpool Overhead Railway Company to erect an additional flight of stairs at the terminal station at the Herculaneum Dock. Mr. Glynn, in moving the adoption of the recommendation, said he was glad to note that the Company already had so many passengers to carry that they required an extension of their accommodation. The motion was approved.

The New York Electric Light Subways.—Those who have placed their wires in the New York electric light subways have had a good deal to contend with, and, now that gas leakage has apparently been rendered harmless, ice intervenes. A short time since when some men opened the Canal-street electric-light subway in order to put a wire in, they found the conduits full of ice. The difficulty was overcome in the following manner:—A bellows, to which was attached a $\frac{3}{4}$in. iron pipe, was rigged up. Around the coils of the pipe a fire was built, and a hot-air blast was directed on to the ice-choked ducts.

The London Telephone Service.—We received the following letter from the Secretary of the National Telephone Company on Friday morning last:—

Dear Sir: I duly received your communication of the 20th instant, and in reply beg to inform you that we contemplate making a reduction in our metropolitan tariff for the connection of private residences for domestic purposes to £10 per annum on a five years' agreement, or £12 per annum on a yearly agreement, where the address to be connected is within one mile of our nearest exchange. An extra charge of £2. 10s. per annum will be made for each extra half-mile beyond the above distance.
Yours faithfully, Albert Anns, Secretary.

P.S.—The reduced rates will not apply within the area comprised in the City of London Union.

Electricity v. Gas at Lyons.—The Lyons Gas Company has, says the *Gas World*, been getting itself into trouble in a curious way. An electric-lighting company was going to supply a particular district of Lyons, and the Gas Company, in order to cut it out, began to supply gas in that district at 22 instead of 30$\frac{1}{4}$ centimes per cubic metre (4s. 11$\frac{1}{2}$d. instead of 6s. 9$\frac{1}{2}$d. per thousand cubic feet). One of the consumers in the town, hearing of this, objected to paying the full price, and claimed an equal reduction. The Court held that the Company had done

Hosted by Google

wrong, and must yield the reduction to every consumer. The Company has appealed.

The Berlin Telephone Exchange.—At the beginning of the present year the 20,000th subscriber was connected to the Berlin Telephone Exchange. The system came into operation on April 1, 1882, with 50 subscribers; by the end of the same year this figure had increased to 458. The following are the totals for the January of each year since:—

1883	1,069	1888	6,955
1884	1,625	1889	9,199
1885	2,412	1890	11,854
1886	4,324	1891	14,490
1887	5,507	1892	17,013
		1893	20,000

Determination of Areas from Measured Diameters.—In a short Paper before the Franklin Institute, Mr. O. T. Louis discusses the effect of errors in calipering cylinders on the areas calculated from the diameters thus measured. He shows that the common opinion that the error in the area is equal to the square of the error in the diameter is erroneous, and that the actual error is never far from double the error of the diameter, when this has been over estimated. An error caused by crushing of a wire by screwing up the calipers gives rise to less error in the calculated area than an error of the same magnitude in excess. The author, therefore, suggests that it is an advantage to err in the direction of a tight measurement.

Books on Indiarubber Manufacture.—"Why does not some one 'in the know' write a book on the manufacture of vulcanised rubber goods?" says *Industries*. "There are many treatises whose externals look as if they dwelt on this subject, but on examination they are found to be written by theoretical rubber people, who make rubber goods of Para rubber and sulphur with no foreign ingredients. 'Real rubber goods' contain very little rubber. Anybody can make rubber goods out of rubber; the real art is to make them with as little rubber as possible. We believe that the mixtures used in rubber works, especially for electric cables, are kept profoundly secret; but if a writer does not know these mixtures, or does not give them in his book, he has no business to publish it. It is obtaining money—and, what is worse, wasting a reader's time—under false pretences."

The National Telephone Company and Electric Traction.—At the last meeting of the Edinburgh Town Council a letter was submitted from the Thomson-Houston International Electric Company, intimating that an Association was being formed for the purpose of resisting the demands of the National Telephone Company for the introduction of special protective clauses in all Bills and Provisional Orders where powers for traction by electricity were sought. The Lord Provost said they all knew how the National Telephone Company was really becoming a source of tyranny, and he was glad to find that other towns were wakening up to the position of affairs. Though they sent the letter to the Lord Provost's Committee with powers, it was not for the purpose of joining the Association, though he had no doubt they would be glad to join if it should seem desirable, but for the purpose of obtaining information on the matter. The letter was sent to the Lord Provost's Committee with powers.

Tanning by Electricity.—In the Pinna process of electric tanning, the hides are submitted to the action of alternating currents while immersed in the tanning liquor. A metal electrode is placed at the bottom of the pit, and the hides are piled one upon the other. The tanning liquor is then run in. The current density required is from $\frac{1}{2}$ to $1\frac{1}{2}$ ampere per square inch, according as the skins are light or heavy. The frequency of the alternations should be not less than 43. The arrangement described can obviously be adopted in the usual pits, but the vertical suspension of the hides side by side between vertical electrodes has given better results, and permits individual hides to be examined during the process. It is claimed that 100 to 400 hours, according to the quality of the skins, is sufficient for the process. According to M. Pinna the advantage of employing electricity at all lies in the fact that it powerfully assists the penetration and diffusion of the tannin into the skins in consequence of the physiogical action which electricity exerts upon the cellular tissues. Continuous currents, resulting in electrolysis of the tannin, give rise, in his opinion, to deleterious reactions.

The City of London Electric Lighting Company.—The City of London Electric Lighting Company were summoned at the Southwark Police Court on Saturday by the sanitary inspector to the St. Saviour's District Board of Works, for that they did on February 27th and March 1st, 3rd, and 6th, send forth black smoke from the chimneys at their station, Meredith's Wharf, Bankside, Southwark, in such quantities as to be a nuisance. Mr. Topham, solicitor, prosecuted, and the Company were defended by counsel. One of the four summonses was taken as a test case. Evidence was given by engineers, experts, and others for the Company to prove that theirs were the very best smoke-consuming furnaces; that only the best Welsh smokeless coal was used; and that the chimneys did not smoke. Inspector Grist and his assistant proved watching from 6 to 6:30 p.m. on February 27th, during which time dense volumes of black smoke were sent forth from the Company's chimneys. Mr. Topham contended that the magistrate was bound to convict, and that it was only necessary for him to prove that black smoke was sent forth, no matter how excellent the construction of the furnaces. Mr. Slade fined the Company £5 and 2s. costs in the first case, and in each of the others inflicted penalties of 10s. and 2s. costs.

Electric Tempering.—In *The Electrician* for February 5, 1892, we gave a brief summary of a communication made by Prof. Lagrange and M. Paul Hoho to the Académie Royale de Belgique, on the subject of the luminous sheath which surrounds a fine wire when used as negative electrode in an electrolytic vessel through which a powerful current is passing. In the *Comptes Rendus* for March 13th the same investigators point out that the sheath is not only luminous but intensely hot, the heat being very local. A piece of iron 10 centimetres long and 1 centimetre in diameter can be heated, by proper arrangement of non-conducting screens, in alternate centimetre long sections, the heated sections fusing while the cool sections are still quite cold. So rapid is this heating action that a rod of iron can be made white hot at the surface before the interior is affected, so that by suddenly making and breaking a circuit, the surface of a piece of iron is suddenly heated up and then quenched in the electrolyte, thus getting an exceedingly hard coating, the depth of which depends on the duration of the process. The authors showed samples of iron which had been treated in this way, and which exhibited totally different fractures at the surface and in the interior. Electrical heating for tempering has been in use for some years, but this process seems to permit the quenching of very fine springs and promises to be useful in case-hardening.

The Pelton Water Wheel.—According to a correspondent of *Power*, the principle involved in the Pelton wheel has a curious history. It was embodied in a turbine invented by Jearum Atkins. In due course, as was then and is now the custom in the Patent Office, the application was rejected. Shortly after, Mr. Atkins was thrown from his waggon and injured. While in that condition, however, he made many inventions, and acquired a competency. Among other things he perfected the details of his wheel, and applied for a patent, which was granted August 10, 1875, No. 166,676. In his application he embodied a full mathematical exposition of the action of the water on the wheel, showing that the entire momentum of the water is imparted to the wheel if it enters, as in the Pelton, at one side of a semi-circular bucket and escapes at the other, the direction of its motion being exactly reversed in transit. Under these conditions the wheel will move with half the initial velocity of the water, and the spent water will fall away without residual velocity. The mathematics of the specification was too deep for the Patent Office examiner, and he required its cancellation upon the ground that it was not necessary. Afterwards he admitted that he did not consider the demonstration necessary, and did not know whether it was true or not. Anyone curious to know will find it embalmed in the original specification of that application. The Pelton wheel embodies the same principle, and if more perfectly formed would realise the full theoretical value of the jet.

ELECTRICITY AS A MOTIVE POWER.*

BY ALBION T. SNELL.

(Continued from page 564.)

§ 2. The Dynamo and Motor.

The author has not thought it advisable to enter into an elementary discussion of the principles underlying the construction of dynamo-electric machines. This is the province of text-books on electricity and magnetism. Here the object aimed at is rather to develop the lines on which these principles are applied in practice, and to give useful information to the construction engineer. Although machines suitable for the transmission of power are chiefly held in view, yet the method advanced is equally applicable to dynamos intended for lighting or other purposes.

First, it is necessary to distinguish between the dynamo and the motor. In the introductory remarks it was mentioned that the dynamo was a reversible machine, the motor being the converse of the dynamo. The functions of the two machines must now be compared. The chief conditions of working in the two cases are widely different, and these distinctions must be duly considered in the design. The dynamo will usually be driven at a speed as nearly constant as possible, and will be required to give a variable output at a constant difference of pressure. The motor will usually be run at a fairly constant E.M.F. of supply, and will be required to give a variable torque at a constant speed. The dynamo in most cases will be placed in a dry engine-room, and meet with at least as much attention and care as ordinary steam plant. The motor, on the other hand, must be in close proximity to the driven machine, and will frequently be in a dusty, dirty, and more or less exposed position; and the attendance will be most likely a few visits daily at the best. The dynamo will probably run with fairly steady loads, and not be subjected to large sudden variations of output. The motor must, in the nature of things, meet with rougher usage. If the work be intermittent, the stoppages frequent, or overloading common, the motor must meet the demand, no matter how great the strain. It follows, therefore, that the motor should be built with a larger factor of safety than is usually necessary with a dynamo; and that extra care should be given to the insulation and general details. To ensure due prominence being given to these conditions, it is the practice of the author to base the design of the dynamo on the total armature E.M.F., and to give special attention both to the maximum and the average torque in the building of the motor.

§ 3. Units and Symbols.

To make the equations suitable for the drawing office, inch-pound-minute units will be used. The author has for some time endeavoured to use the C.-G.-S. system in dynamo design; but he has invariably found it necessary to convert the measurements into English quantities before the drawings can be used in the shops, because the workman uses a foot-rule and thinks in eighths and quarters of an inch. The decimal system is admirable, but it has not taken in this country; and until it has there is nothing to be gained by making the duplicate measurements. To the pure physicist the C.-G.-S. system of units offers a real advantage, for it simplifies his work; but to the construction engineer, at present at any rate, it only means an increased number of figures with a corresponding chance of error from clerical slips. The symbols will be as nearly as possible those used in the fourth edition of Prof. Silvanus Thompson's "Dynamo-Electric Machinery," because these are no doubt already widely used, and so will be readily followed by the majority of men interested in the subject.

Symbols used in the following Calculations and Equations.

A = area in square inches.
$A T_s$ = ampere turns with armature on open circuit. } Both refer to field
$C T_s$ = compensating ampere turns for full load. } magnets.
B''_a = the magnetic induction per square inch of armature cross section.
B''_f = the magnetic induction per square inch of field-magnet cores.
B''_g = the magnetic induction per square inch of the area of the air gap.
N_a, N_f, N_g = the total magnetic fluxes severally in the armature, field-magnet, and air gap.
C_a = the total number of conductors in the armature, counted all round the external periphery, and therefore applicable to either drum or gramme winding.
C_s = the total number of turns of wire on the shunt coils of the field-magnets.
C_m = the total number of turns of wire on the main or series coils of the field-magnets.
D = the outer diameter of the armature,
d = the inner diameter of the armature,
r = radial depth of the iron of armature,
l = the length of the armature reckoned over the iron, } in inches.
E = the total electromotive force generated in an armature, either dynamo or motor,
e = difference of potential from terminal to terminal, } in volts.
η = efficiency or economic coefficient.
F = force (push or pull) in pounds weight.
i = current in external circuit,
i_a = current in an armature,
i_s = current in shunt coils,
i_m = current in series or main coils, } in amperes.
μ = coefficient of magnetic permeability.
n = number of revolutions per minute.
p = number of pairs of poles.
R = resistance of external circuit,
r_a = resistance of armature coils,
r_s = resistance of shunt coils,
r_m = resistance of series or main coils, } in ohms.
T = torque or turning moment.
v = coefficient of allowance for magnetic leakage.
δ = length of the air gap *on one side only*,
w = width of the polar cavity,
L_g = length of the polar cavity,
m_a = mean length of magnetic path in armature core,
m_f = mean length of magnetic path in cores and pole pieces, } in inches.
m_{f1} = mean length of magnetic path in yoke,
W = work per minute in foot-pounds.

§ 4. First Approximation to the Size of Armature for a given Output and Speed.

The first point to determine in designing a dynamo is the size of armature that is best suited to meet all the requirements of the problem. Usually the volts, amperes and speed are fixed, and frequently the selling price too. The latter cannot be specially discussed, but a few hints gathered from practice will be given when possible. We know, then, e, i and n. The size of machine can generally be selected by reference to a price list, and by making a few rough calculations. But if the type be new to the shop, no data are available, and it is necessary to resort to a few figures and to solve a few simple equations.

The output of any dynamo is proportional to the volume of the armature, the number of revolutions per minute, and the magnetic flux. Hence output $\propto l D^2 n \mathbf{N}_a K$, where K is a dimensional constant to reduce the product to watts or horse-power. The author first published empirical equations of this form in 1888, and coupling $\mathbf{N}_a$ and K he based the resultant value on an average magnetic density and radial depth of core. Such assumptions are found to be fairly correct for the greater number of bipolar machines with outputs of from 10 to 100 H.P.; but below and above these limits the equations are not so nearly in accord with actual results. Small machines realise smaller outputs than this theory indicates, owing to the disproportionate resistance of the air gap; while in large machines the output is so largely affected by the design of the field-magnets and the arrangement of the poles that separate calculations are needed for every type. Nevertheless, similar equations can easily be determined for any size and type, but the constant must be adjusted to suit the conditions. For gramme armature dynamos the author finds the coefficient 0·01 to give fair results between the limits stated; and for drum machines 0·015, the output in each case being in watts. Thus for dynamos:—

$$\text{Watts} = l D^2 n\, 0{\cdot}01 \text{ (gramme)}, \quad . \quad . \quad . \quad (1)$$

$$\text{Watts} = l D^2 n\, 0{\cdot}015 \text{ (drum)}, \quad . \quad . \quad . \quad (2)$$

and for motors, estimating the output in brake horse-power:—

$$\text{B.H.P.} = l D^2 n\, 0{\cdot}00001 \text{ (gramme)}, \quad . \quad . \quad (3)$$

$$\text{B.H.P.} = l D^2 n\, 0{\cdot}000015 \text{ (drum)}. \quad . \quad (4)$$

It should be noted that a drum armature is capable of giving an output which is 50 per cent. in excess of a gramme ring of the same over-all dimensions. This enormous advantage in the weight efficiency of drum armature machines is

* All rights reserved.

Hosted by Google

well recognised, and where the conditions of running admit of the design it should be invariably used. Indeed, if it were not for the difficulties in the winding and insulation of drums, gramme armatures would soon be obsolete. The superiority of the drum lies chiefly in the following points: (*a*) it has no inside wires to cause an internal field, as well as to increase the dead resistance of the winding; (*b*) there is less inequality of E.M.F. in the coils, since each turn of wire embraces the whole armature field; and (*c*) the iron can be carried right to the shaft, and therefore the magnetic induction per unit of area may be made low, though the total flux is very large.

The gramme winding, although causing an internal field and a more irregular distribution of the lines of force, is better adapted for rough work, since coils of very different potentials are not in close contact, as occurs with ordinary drum windings. There are arrangements of bar windings with specially shaped end connections which obviate this objection to some extent; but experience has all along pointed to the gramme type of winding as the safer for hard work. The author has tried both methods, and has no hesitation in advising the gramme winding for high-tension transmission dynamos and motors. For lighting, dynamos of, say, from 100 to 200 volts, the drum type, with bar windings, and spiral strip connections, is the better, and is generally adopted now when other considerations do not prevent its use.

The rough dimensions of the armature for dynamo or motor may now be assumed to be known, and the calculation of the winding may be proceeded with.

§ 5. Fundamental Equation connecting the Total E.M.F. with the Armature Constants.

The factor of prime importance in armature design is E, the total E.M.F. The value of E is determined by the relationship—

$$E = e \pm i_a r_a. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

The positive sign must be used for the armature of a generator, and the negative for that of a motor. The armature current i_a is known from the conditions of the problem; but r_a has to be determined, as the winding is not yet chosen. An assumed value must be substituted in (5), which can be amended when the gauge and number of turns of wire are definitely fixed. The numerical value of $i_a r_a$ cannot be given, but can be conveniently expressed as a percentage of E. The following table of approximate values will be of use at this stage:—

Table A.

Output of dynamo or motor in H.P.	$i_a r_a$ expressed as a percentage of E.
2·5	6 per cent.
5	5·5 „
10	5 „
15	4 „
20	3 „
25	2·75 „
30	2·5 „
50	2·25 „
100	2 „

The total armature E.M.F. is given by

$$E = C_a \mathbf{N}_a n \frac{10^{-8}}{60}. \quad . \quad . \quad . \quad . \quad . \quad (6)$$

C_a, the number of turns of wire counted all round the periphery, is the most important variable; n is the number of revolutions per minute, and is given by the conditions of running. $\mathbf{N}_a$ is the total magnetic flux, and is numerically equal to the product of the number of square inches in the cross section of the armature and the magnetic density per square inch, or

$$\mathbf{N}_a = \mathbf{B}_a'' 2 r l 0{\cdot}85. \quad . \quad . \quad . \quad . \quad . \quad (7)$$

The coefficient 0·85 is introduced to allow for the insulation between the plates of the armature.

The value of l was fixed when the over-all dimensions of the armature were chosen; and so in practice would that of r be; for the radial depth of core has presumably a fixed ratio to the diameter of armature for a given type of field-magnet. Various considerations determined by experience fix the magnetic flux per unit area at from 90,000 to 110,000 lines of force. Therefore $\mathbf{N}_a$ can readily be determined as soon as the size of armature is selected.

(To be continued.)

LIGHTNING ARRESTERS IN THE UNITED STATES.

BY ALEXANDER JAY WURTS.

During a trip made last summer through various sections of the United States, I took especial pains to note the troubles that were experienced by electric light and power plants during thunder storms. In the eastern states thunderstorms seem to be local, and I repeatedly found electric plants within 50 miles of each other, where in the one case troubles from lightning were incessant, and in the other a thunderstorm was almost unknown. From Chicago, Ill., all the way to the western coast frequent thunderstorms seem to be taken as a matter of course, but these were particularly violent along the valley of the Mississippi and in the neighbourhood of the Rocky Mountains. A certain plant in the state of Illinois reported the loss of over 30 converters during a single storm. Further west, the loss of four or five converters during a thunderstorm was a common occurence. The destruction of electric railway apparatus was not so frequent, but this was largely due to the fact that at the first sign of approaching trouble, trollies were tied down and the switches at the station thrown out till all danger was passed. The pecuniary loss is, nevertheless, considerable even under such circumstances, for not only are the net profits to the company severely curtailed, while expenses still run apace, but there is also great loss in public confidence. In Colorado there is a large electric railway plant that is forced to shut down for an hour or two nearly every afternoon during the months of June, July, and August. Still further back among the mountains are many alternating-current plants operated by water-power, and these are reported as being almost inoperative during the afternoons of the summer months. It will thus be seen how vitally important an efficient lightning arrester is in this country of thunderstorms.

There are two general methods of protecting electric systems; one is by means of the simple discharge circuit containing a spark-gap and connected directly from line to earth. Disruptive discharges, however, form nodes, where there is little or no tendency to discharge. If, then, a spark-gap arrester be connected at a node, a discharge will be more likely to occur at some other point. These nodes are constantly shifting their positions in the system; it is evident, therefore, that efficient protection by means of spark arresters can only be secured with any degree of certainty by distributing a large number of arresters throughout the system. I recommend three or four per mile in particularly exposed districts. The subject of these nodal points is a complicated one, and a discussion of it here would be out of place. The other method is to prevent the accumulation of charge on the line by stretching, near and parallel to the line to be protected, a bare wire thoroughly grounded at frequent intervals. The overhead grounded wire forms, as it were, a shield to inductive effects, and, at the same time, tends to equalise the difference of potential that would otherwise exist between the neighbouring atmosphere and the earth. The first method is a cure, the latter a preventative. Both of them involve difficulties; the latter is the more efficient of the two.

When spark-gap arresters are connected to both legs of a circuit, a discharge will almost invariably take place from both legs at the same instant, thus causing a short circuit on the generator. A spark-gap arrester must, therefore, be so designed that it will instantly interrupt this short circuit and automatically adjust itself in readiness for a succeeding discharge. This would not be a difficult matter were it not for the fact that electromagnetic devices offer an enormous resistance to the passage of a discharge. Many devices have been brought out and patented which should accomplish the desired end, but nearly all have combined one or more serious objections—such as moving parts and general complications. A spark-gap arrester to be reliable must be simple, cheap, free from moving parts, and certain to instantly interrupt the short circuit without injury to itself or other apparatus, and without blowing fuses. The non-arcing arrester meets all these requirements for alternating-current circuits. More than a year ago, I discovered that if the electrodes of a spark-gap arrester were made of certain metals, it was not possible to maintain an arc across the spark-gaps when connected to an alternating-

Hosted by Google

current generator. In a Paper read by me before the American Institute of Electrical Engineers, on March 15, 1892, under the title of "Lightning Arresters and the Discovery of Non-Arcing Metals," will be found detailed information regarding this discovery and the remarkable properties of these metals, which are zinc, antimony, bismuth, cadmium, and mercury. The electrodes used in the non-arcing metal arrester are made of zinc, combined with a certain proportion of copper.

An arrester of this kind is illustrated in Fig. 1. It is made double-pole, so that it may be connected to both legs of the

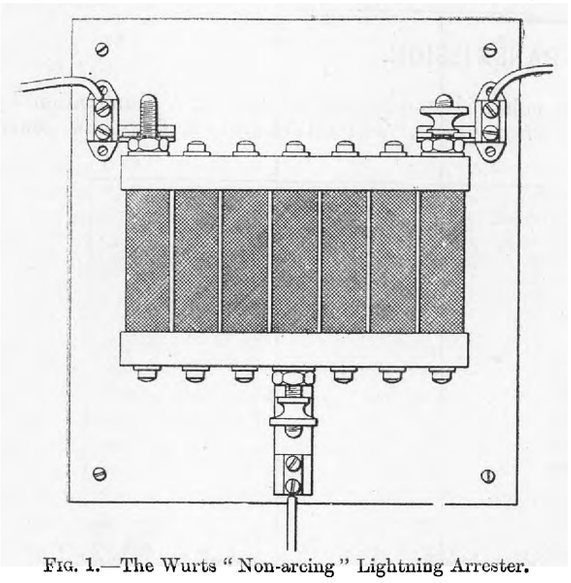

FIG. 1.—The Wurts "Non-arcing" Lightning Arrester.

circuit, and consists essentially of seven non-arcing metal cylinders, each three inches long and one inch in diameter. The cylinders are solid, knurled on the surface, and are mounted on a white marble back with their axes parallel to each other, and are separated from each other by $\frac{1}{64}$th of an inch. When in service, the two outer cylinders are connected respectively to the two legs of the circuit, and the middle cylinder to the ground. There are, therefore, between line and ground three air gaps of $\frac{1}{64}$th of an inch each.

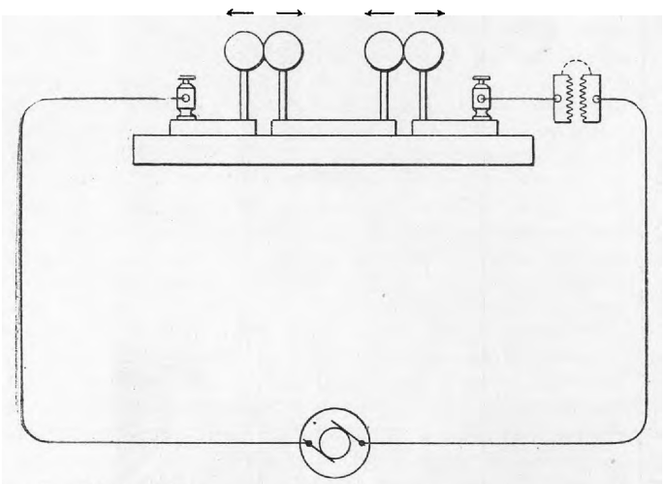

FIG. 2.—Diagram of Arrangements for Experimenting on the "Non-arcing" Property of Certain Metals.

In testing this arrester, the two outer cylinders are connected to the terminals of a 1,000-volt alternator, in series with a switch, the air spaces are bridged with small crumbs of tinfoil, and the switch thrown. The short-circuit thus established is so instantly interrupted that a 20-ampere fuse placed in series with the arrester will not be melted, and often three or four of the tinfoil crumbs will remain intact. The remarkable properties of this metal are, however, more emphatically illustrated by the following experiment: I have mounted two pairs of these cylinders on thermostatic supports (*see* Fig. 2) in such a manner that the two cylinders in each pair normally rest in contact with each other, so that when this device is connected across the terminals of a 1,000-volt alternator, a short circuit is established through the four thermostats and the non-arcing metal cylinders in series; also in such a manner that upon the passage of the current the thermostats shall so act as to separate the two cylinders from each other in each pair. With this device a short circuit is automatically opened and closed every two or three seconds, without injury to the electrodes. If a spark-gap be connected in the circuit and bridged with a bit of tin foil, the short circuit will be instantly interrupted, and, of course, remain so. Perhaps the most remarkable feature about this metal is that it manifests non-arcing properties only when the air gap is very small, in fact, the smaller the better. If the air gap is increased to about half an inch, the short circuit will be maintained with a large and vicious arc.

During the past season, over 2,000 of these non-arcing arresters have been in actual service in various sections of the United States, and so far not one of them has failed. More of them would no doubt have been used and much valuable property saved, had it not been that many central station managers were loath to try any such radical departure from past practice. They feared that the non-arcing metal might not be all that it was represented.

For direct-current circuits the field is still open. Many useful and ingenious devices are, however, already on the

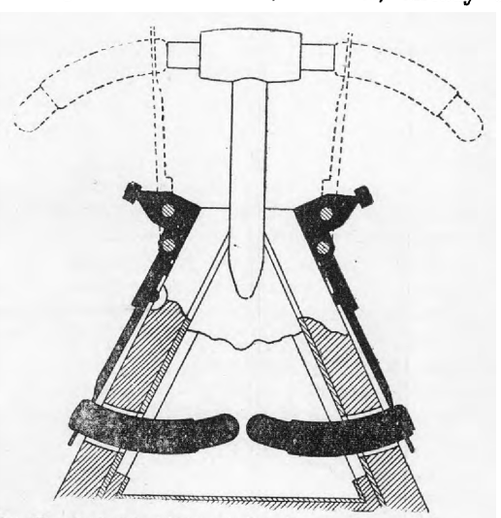

FIG. 3.—"Air-blast" Lightning Arrester. Latest form.

market, the most recent being the "Tank Arrester" described in *The Electrician* for December 2, 1892. The spark-gap arresters most commonly used on street-railway circuits are the "magnetic blow-out" and the "air-blast" arresters. The former is unreliable. Before the magnet has time to act, the electrodes of the spark-gap often become fused together and a permanent short circuit is established. The latter, often called the "keystone" arrester, has the objectionable feature of moving parts. It, however, gives excellent satisfaction when properly installed. This arrester, the latest form of which is illustrated in Fig. 3, has swinging electrodes. These are seen on either side of the keystone-shaped air chamber, and are forced into the positions shown in dotted lines by the sudden expansion of air within the air chamber, the expansion of air being due to the arc formed at the spark gap. The spark-gap is seen located centrally within the air chamber. As this arrester depends for its action on a short circuit, it is necessary that a thorough short circuit should be established each time a discharge takes place. To secure this end, the ground terminal of the arrester should be connected to the rail or ground-wire return of the generator, as well as to a ground plate.

As already mentioned, the over-head ground-wire method is the more efficient and generally available one for the protection of over-head circuits, the chief difficulty which it presents being the fact that the "live" circuits are thus brought into close proximity to the ground. Not only does this combination often endanger the linemen, but it also renders the system

Hosted by Google

liable to trouble from accidental contact between the line and ground wires. In a number of instances familiar to me, and in which lightning troubles have been particularly severe, the over-head ground wire has been used with most satisfactory results. In one instance a barbed wire was stapled to the tops of the poles and grounded about every 700ft. by running connecting wires 5ft. or 6ft. into the ground. Before this wire was erected the plant was almost inoperative during thunderstorms; and now, although spark-gap arresters are still connected at the station, they are seldom called upon to discharge the line; an occasional snap is heard, but no trouble is experienced whatever. In large cities where the overhead wires are protected by high buildings and church spires, lightning arresters are seldom used, or if so, merely as extra precaution. It is also noticed that when arc and incandescent circuits are run on the same pole line, discharges occur from the arc-circuit arresters, while the incandescent circuits are comparatively free from trouble.

THE TIVOLI–ROME TRANSMISSION.

When, in 1888, the demand for electric light in Rome was assuming some importance, M. Pouchain, the Director of the Roman Gas Company, wisely decided to have the new system as an ally rather than as a competitor. The Company registered their enlarged undertaking as one for "illumination by gas *and other systems*," and established a first-class generating station on the Ganz system. About this time, however, the project was formed of deriving power from the falls of the

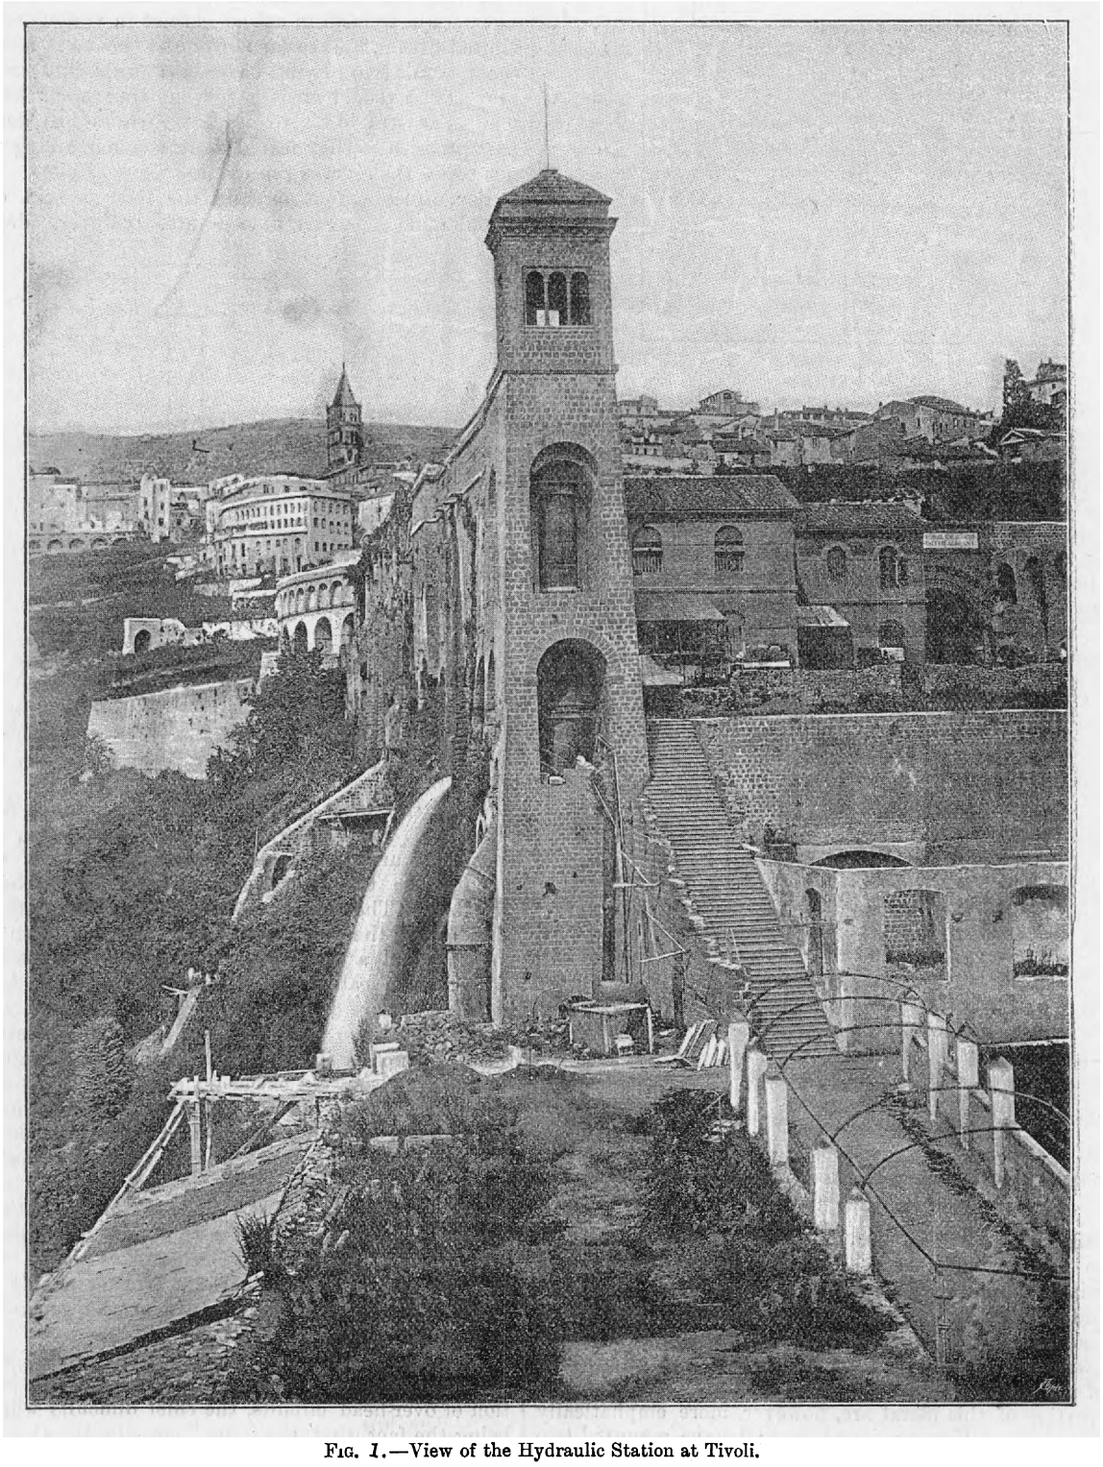

Fig. 1.—View of the Hydraulic Station at Tivoli.

Hosted by Google

Anio at Tivoli. This plan was successfully carried out and finished in July, 1892.

A description of the Tivoli generating station was given in Dr. Fleming's articles on Alternating-Current Electric Supply Stations in *The Electrician*, Vol. XXVII, p. 608. The illustration, for which, together with this information, we are indebted to *L'Elettricista*, shows the tower at the end of the aqueduct conveying the water from the falls, the machinery being below to the left of the observer's position. The iron tube descending through the tower is 5 feet in diameter, and gives a head of water of 160 feet, a fall of as much again being at present unutilised. The water is distributed among nine Girard turbines, coupled direct to Zipernowsky alternators, and three smaller turbines driving the direct-current exciting dynamos. The larger turbines have a diameter of 6 feet 6 inches, run at 170 revolutions per minute, and develope 350 H.P.

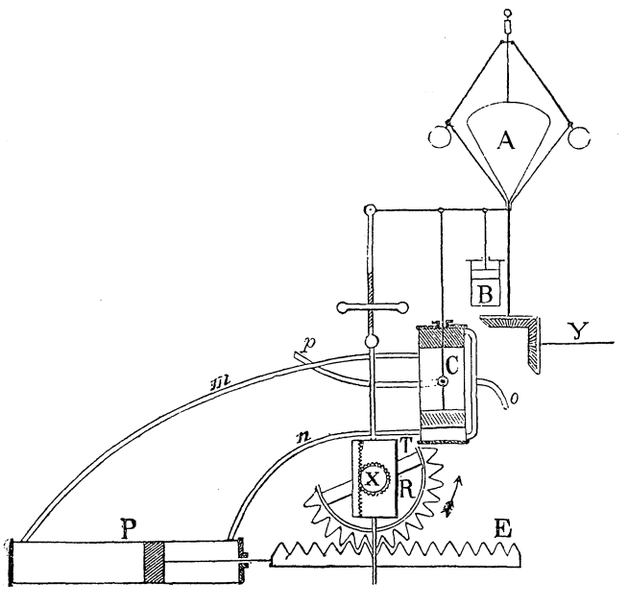

FIG 2.—Automatic Water Supply Regulator.

The water supply is regulated automatically by means of the contrivance shown in the figure. A is a centrifugal governor actuating a slide valve C regulating the pressure supplied through P. The tubes *m* and *n* lead to the two ends of the cylinder P, containing a piston driving a rack E and pinion R. A rotation of the axis X of the latter opens or closes a series of cocks controlling the supply to the turbines. After the action of the slide valve in either direction, it is restored to its original position by means of the rack and pinion motion T, which raises or lowers the fulcrum of the governor lever.

The alternators, which are coupled to the turbines direct by means of an elastic coupling, give a pressure of 5,100 volts. The normal current is 42 amperes. The diameter of the revolving field magnet is 7 ft. 7 in., and there are 30 poles.

PHOTOGRAPHIC DEVELOPMENT BY ELECTROLYSIS.

The reduction of sulphurous acid or an acid sulphite by means of zinc, gives rise, as is well known, to the formation of the salts of an acid in a lower state of oxidation than sulphurous acid, and, therefore, termed hyposulphurous acid. It must not be confused for a moment with the body popularly and commercially known by this name, or rather by the name of its salts, the so-called hyposulphites, familar to the practical photographer by the endearing abbreviation, "hypo." The latter substance is properly thiosulphuric acid, and its salts are, therefore, thiosulphates. True hyposulphites are much less common, their industrial use being chiefly in the preparation of a form of indigo vat of tolerably recent introduction in which the indigo is reduced to the condition of indigo white by their operation. The difference will be at once apparent on writing the formulæ for the real and the pseudo-hyposulphite of sodium. The former is $Na_4 S_2 O_4$ (until lately it was supposed to be $Na H S O_2$), and the latter is $Na_2 S_2 O_3$. The reduction of an acid sulphite can also be effected by electrolysing its solution, hyposulphite appearing at the cathode. Now, like many reducing agents, sodium hyposulphite can act as a developer to a photographic image, a fact that was observed in 1886 by Eder. The negatives thus developed are very soft and full of detail, and are grey in tone, but not so bluish grey as those developed by ferrous oxalate. On account of the ease with which sodium hyposulphite is oxidised by exposure to the air, no practical use has hitherto been made of this observation, but a simple variation in the procedure by R. E. Liesegang, described by him in the *Photographisches Archiv*, has recently brought it into a more workable form. This modification consists in electrolysing a nearly saturated solution of acid sodium sulphite in the developing dish, the cathode being a platinum plate dipping direct in the dish, and the anode being contained in a porous cell and thus the oxidised products appearing thereat prevented from mixing with the hyposulphite produced. The current given by half-a-dozen Gassner dry cells suffices for reducing the acid sulphite. On immersing a fully exposed bromide plate in the bath, an image, brownish red in tone, is developed in the course of a few minutes, the oxidation of the hyposulphite by the air or by the work of development, being made good by its being immediately reduced again by the action of the current. The image is not very strong, and fades somewhat on fixing, but it retains its characteristic colour. It is curious that there is a discrepancy in the accounts of the colour produced, given by Eder and Liesegang; the cause is probably a difference in the nature of the sensitive film. It is obvious that the same plan of electrolytic development could be applied to other bodies, such as hydroquinone which could be reduced from quinone, but as in this case the less oxidised bodies are more stable than sodium hyposulphite, they can be prepared by ordinary chemical means and used as wanted, instead of being produced at the moment of development.

THE ELECTRIFICATION OF GASES BY FRICTION ON METAL.*

The question whether gases become electrically charged by friction against metal has been taken up by many investigators, some of whom have answered in the affirmative and some in the negative. The experiments of Faraday and of Sohuke among others are so far open to objection, that the gases were not sufficiently carefully dried and filtered from dust. The author took air, compressed to 100 atmospheres pressure, also pure oxygen supplied by the Elkau compressed oxygen factory (Berlin), and liquid carbon dioxide supplied by the Berlin Carbonic Acid Company.

The method of experiment was in general that of Faraday. The tube through which the gas was forced out of the holders had an enlargement in the form of a funnel, in which a metal plug fitted, which was connected to the electrometer. Funnel and plug were in a tin box. Air which contained moisture and dust was found capable of being highly charged by friction on metal; but this property became as small as one pleased if the air were thoroughly dried and filtered; so that it may be assumed that with pure air there would either be no effect at all, or very little. Oxygen was found to behave similarly to air in the purified state. Liquid carbon dioxide charged the metal positively, but in the gaseous form was not found to be affected by friction.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

THURSDAY, April 6th.

INSTITUTION OF CIVIL ENGINEERS.

2:30 p.m. Students' visit to the new lock and weir works, at St. Margarets, Richmond.

FRIDAY, April 7th.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Smoking Concert at St. James's Hall Restaurant.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

* Abstract from Paper by K. Wesendonck (*Wied. Ann.*, No. 12, 1892)

Hosted by Google

CRITICISM.

'When critics disagree," says a brilliant but superficial paradoxist, "the artist is at one with himself." This disagreement is, perhaps, one reason why a criticism seldom draws a rejoinder. Another reason for ignoring the opinions of critics is that they often make no pretence or attempt at producing any original work. "The talent of judging," wrote D'ISRAELI the elder, "may exist separately from the power of execution. An amateur may not be an artist, though an artist should be an amateur. And it is for this reason that young authors are not to contemn the precepts of critics." In the field of science, fortunately, the critic does not set himself up as a professional arbiter and connoisseur as in the arts; scientific reviewers, however, are generally engaged on actual work of the kind which they are called upon to examine. Reviews form an important part of current literature, their importance being attributable, perhaps, to the laziness of readers who prefer to skim pages rather than volumes. But what author is really satisfied with anything but praise, and who will admit, when pointed out by someone else, the weak argument or faulty passage of which he has long been fully conscious himself? "So men are valued!" wrote BURTON, "their labours vilified by fellowes of no worth themselves, as things of nought; who could not have done as much? Some understande too little, and some too much."

Many *leges non scriptæ* go to make up a code of conventions which tradition has fastened upon literature, and for some reason that is not easy to discover there appears to be a reluctance on the part of authors to reply to the criticisms of reviewers. We are inclined to regard this, however, as a mere custom, and that a bad one, if only because the reviewing of books is one of the only opportunities that is allowed by custom for free and candid comment. One other opportunity

Hosted by Google

is afforded in debate, and in the course of discussions at the meetings of scientific societies free criticism is allowed, and is not considered offensive. Every facility is given for reply in the latter case, and there is no reason why it should not be granted in the former. Favourable criticism seems to be peremptorily demanded in a good many cases when the article submitted for "notice" is a new switch or a price list, and the mildest comment in such cases, if anything else than laudatory, appears to give more offence than a column of slashing reviews of worse than useless books. Criticism seems to be considered out of place by some in a description of a new central station, but where an opportunity is given for reply, it is difficult to see what harm can be done; for harm can come of it only by unjust or mistaken comments, or perhaps by an ambiguity of phrase unthought of by the writer but wounding a too sensitive reader. Reviewers, it is to be regretted, too often shelter themselves behind an ambush of anonymity, are too seldom called to account for thoughtless utterances, and are rarely challenged to support doctrines which they have lightly sketched in opposition to the carefully-considered convictions of the author. At present there seems to be no choice for the injured person but speechless disdain or a costly libel action.

REVIEWS.

Electric Ship-Lighting. By J. W. URQUHART. (London: Crosby Lockwood and Son.)

The information in this book is well arranged and up to date; and numerous practical hints and diagrams are given for the assistance of engineers. Electric ship-lighting may be classified under three heads: (1) Internal incandescence lighting; (2) arc lighting for navigation purposes; and (3) arc lighting for naval attack and defence. The first of these differs from ordinary low-tension wiring chiefly in the use of an "earth" or ship return, and in the difficulties which are encountered in connection with water-tight bulkheads and magnetic compasses. By far the greater portion of Mr. Urquhart's book deals with this department of lighting; the subjects of wiring, fitting, testing, and the choice and arrangement of lamps, switches, and cut-outs being dealt with in a practical fashion. The text is assisted by numerous illustrations, and the value of the information enhanced by a worked-out example of the wiring of the s.s. "Majestic," of which vessel a frontispiece is given. Chapters I. to IV. deal with preliminary arrangements—such as the choice of a system, plant, and attendant—and with the management of the machinery during running or at a breakdown. Chapter IX. treats of the use of accumulators, and describes one or two accumulator systems. Arc lighting is more particularly deal with in Chapter V., though the early chapters relate to this as well as to glow lighting. In this chapter several forms of arc and search lamps are described. The use of this form of light for naval attack is, however, barely mentioned, although the arrangement of circuits and projectors on men-of-war is essentially different from that on vessels of the mercantile service. It is an astonishing fact that automatic lamps have never seriously replaced hand-fed, hand-regulated projectors, either on naval or commercial vessels. Some very ingenious automatic-fed projectors, which can be electrically controlled by an operator at a distance, have, we believe, been fitted on one or two ironclads. But the fact that these have not been very successful is, we suppose, the reason why no mention is made of them in this treatise. An introduction on electric theory is intended to prepare the beginner for the practical part of the book. We think, however, that before attempting to study electric ship-lighting, a beginner should learn more of the principles of the science than could be given in such an introduction. After that, if he takes up Mr. Urquhart's book, he will do well.

Electric Light: Its Production and Use. By J. W. URQUHART. (London: Crosby Lockwood and Son. Fifth Edition.)

The demand for a fifth edition is in itself considerable evidence of the value of this work, and a proof that it meets the requirements of a certain class of readers. Mr. Urquhart has essayed a very difficult task in this book, in combining a historical account of the evolution of electric light machinery, from its most remote stages, with a scientific explanation of the principles and practice of modern electric lighting. The difficulty—one may almost say, danger—lies in yoking the two things together; for, like a couple of ill-matched steeds, they do not run well. Or, like the camel and the Arab in the fable, the one it apt to squeeze the other out of existence. Indeed, these two sections of the book appeal to two very different classes of readers. The beginner who finds it necessary to study the chapters on primary batteries and elementary mathematics, is not in search of obsolete arc lamps or primitive dynamos; he looks for descriptions and drawings of types now actually at work. On the other hand, the scientific antiquarian, patentee or expert who may need to explore the past, has no necessity to do so by wading through descriptions of Bunsen batteries and methods of jointing. With due consideration of the cry of "privilege" which we notice in the preface, we still think that a work under the above title should have more complete information on modern practice and less of the lumber of the past.

Polyphased Alternating Currents. By E. HOSPITALIER. (London: Alabaster, Gatehouse and Co.)

At the time these articles were originally written, it was quite correct to say that "The question of polyphased alternate currents has become the topic of the day," but it is far from true at present. The Lauffen-Frankfort experiments drew general attention to a system of transmission previously unknown, and with the close of the Frankfort Exhibition, interest in this subject has to a very great extent dropped out of existence. After all, the main interest in the experiments centred in the possibility of transmitting a large amount of power efficiently over a distance of a hundred miles, rather than in the method of transmission employed. Nevertheless, the work which has been done with polyphased currents is of general interest, and forms the most important attempt yet made to solve the problem of alternating motors. The polyphase systems of electrical transmission are, perhaps, only transitory, but they have constituted a new development of electrical industry, the final importance of which no one can as yet foretell.

The present little work is a description in very simple language of polyphase machinery. It is mainly concerned with the dynamos, motors, and transformers used in the Frankfort transmission experiments. The style is clear, the book is well illustrated, and the printing is good. The work is mainly descriptive, little or no attempt being made to put forward theoretical views, and all mathematical argument is rigidly excluded. There is very little criticism in the book, but it contains much useful information, and may be confidently recommended to those interested in the subject. Two appendices are added, the first containing all the experimental results which have as yet been published regarding the Frankfort experiments; the other being a reprint from the *Electrical Review* of a valuable article by Mr. Reckenzaun, containing particulars of the Heilbronn-Lauffen plant used for transmitting 900 H.P., by polyphase currents, over a distance of 12 kilometres.

Die Accumulatoren zur Aufspeicherung des Elektrischen Stromes, deren Anfertigung, Verwendung und Betrieb. By J. ZACHARIAS. (Jena: H. Costenoble, 1892.)

This book is another of the compilations of patents, and articles which have already appeared in the technical Press, to which the Germans are gradually accustoming us. To anyone who does not possess Hoppe, and is in need of a well illustrated collection of descriptions of the principal forms of cells in use, and which have been introduced from time to time, the book will be of service. There are the customary chapters on the arrangement of cells for the different uses to which they have been put, and the methods employed

Hosted by Google

for their regulation; the results of efficiency tests on various makes of cell are given, and the author has also collected some data on the effects of changes of temperature on the working efficiency of cells employed in central stations. This is a point on which more information is much required, as it would help to elucidate many of the difficulties connected with the chemical theory of the action of accumulators.

Telegraphic Connections, embracing recent methods in Quadruplex Telegraphy. By C. THOM and WILLIS H. JONES. (New York: D. Van Nostrand. London: E. and F. N. Spon, 1892.)

This is an admirably-written and well-printed account of the modern American ways of using the polar-relay and other instruments in duplex and quadruplex telegraphy. It is of little use to European electricians, as it assumes the American closed circuit system as the basis of operations, and makes the statement—astoundingly untrue for all the rest of the world—that until 1872 this was the only method of telegraphy in general use! The writers appear never to have heard of Gintl or of Heaviside, for they credit duplex and quadruplex telegraphy to American electricians whose respective work was of later dates. One interesting feature of the book is the connections used when dynamos are employed instead of batteries at a central telegraph office. Twenty plates, some printed in colours, clearly show the numerous circuits and their connections.

Carte Générale des Lignes Télégraphiques Internationales. By MM. PAUL JACCOTTEY and MAXIME MABYRE and M. ÉMILE LEVASSEUR. (Paris: Institut Géographique Ch. Delagrave, Rue Soufflot.)

This is a coloured map designed to show the submarine cables of the world, and also, as far as the information is obtainable, the land-lines of the various states and companies. The map is dated November, 1892, but the mileage figures given for a large number of the cables are in many cases inaccurate. The figures appear to coincide with the statistics given in "The Electrician" Electrical Trades' Directory and Handbook for 1890 or 1891, the lengths of the cables more recently laid not being included. So far as we have checked the figures, this seems to be invariably the case. Amongst the cable-owning companies included in the list is the India Rubber, Gutta Percha, and Telegraph Works Company, which is credited with three cables of a length of 145 nautical miles. The Eastern Telegraph Company's cables are shown with a total of 25,374, instead of 25,896 nautical miles, the Cuba Submarine Company's figures as four cables with a mileage of 1,049, which should be five cables and a mileage of 1,500 nautical miles. The list does not include the South American Company's cables at all, although coloured in the map. Notwithstanding this incompleteness, however, the map will be found useful.

A NEW DÉRI ALTERNATE-CURRENT MOTOR.*

A new alternate-current motor has been constructed by Max Déri on the principle shown in Figs. 1 and 2. The armature coils are not all connected together, as in the case of the direct-current dynamo, but the two ends of a coil (or parallel or series group, which is symmetrically placed in the field, such as s_1 s_2 in Fig. 1) are connected to two corresponding collector sections and insulated from all the other coils and sections. The coils or groups of coils so arranged come one after another into contact with the brushes, two or more such groups being put in parallel as the brushes pass the sections; it is said to be a good arrangement to send current into several of the circuits at once, but the circuits must be such as to have about equal electromotive forces. Fig. 3 shows an arrangement by which the circuits are spread nearly evenly over the armature, which is desirable; the arrangement is self-explanatory; the current causes consequent poles at the points where it enters and leaves. Fig. 4 shows another kind of winding. The principle is the same as that of an old arrangement of Déri's; it consists in reversing the winding at points equidistant from both leading-in and leading-out points—in this case the armature is divided into twice as many portions as there are magnet poles—and the result will be noted that the consequent poles are now formed at those reversing points at which the leading-in and out wires are not joined on. It will be noted that since, in these methods of construction, the armature coils are always in parallel, the simplification indicated in Fig. 2 becomes possible—viz., that one end of each circuit can be joined to a common collecting ring or similar arrangement of some kind.

In all these forms the working current flows through the coils so placed on the armature that the poles hereby caused are in such a

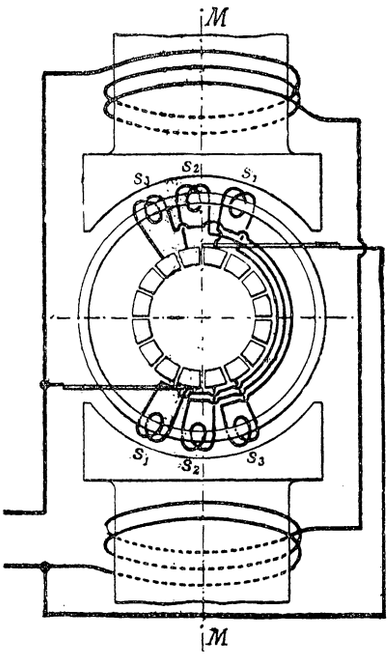

FIG. 1.

position as regards the field poles as to produce the maximum torque. It will be noted that since the armature coils are only intermittently traversed by current, it is possible to use a correspondingly higher current density than is allowable in the case of a direct-current dynamo or motor for the same amount of heating; and this fact enables a high efficiency to be obtained in spite of the fact that a portion of the armature is lying idle.

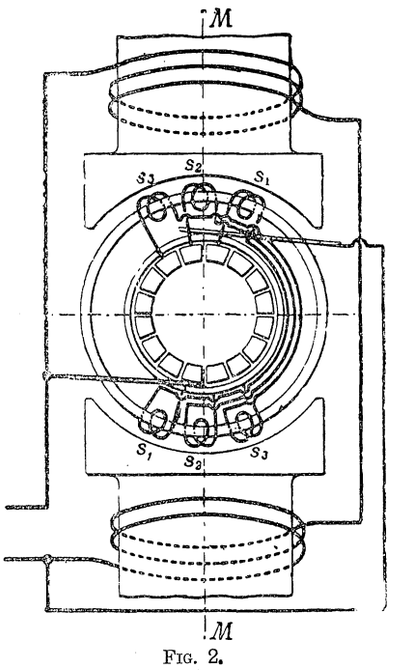

FIG. 2.

The theory of the action is explained as follows:—The armature in such a machine, where both field and armature are traversed by alternating currents, may be said to be subjected to two inductive influences—first, the inductive action due to the change of induction in the fields, which is independent of the motion of the armature, and secondly, the inductive effect due to the rotations, which depends on the speed. Fig. 5, gives a graphic representation of the two effects, showing the electromotive forces due to each. The abscissæ are lengths of arc round the armature, starting from the

* Abstract from the *Zeitschrift für Electrotechnik*, March 1, 1893.

Hosted by Google

line M M as zero, and the ordinates are the electromotive forces on the connector wires at corresponding points. The voltage due to the change of field-magnet strength is greatest at 0deg., and becomes nothing at 90deg. from this point.* On the other hand, the electromotive force due to rotation is greatest at 90deg., and least at 0deg. The resultant pressure is determined at 0deg. by the change of field, and at 90deg. by the speed of rotation.

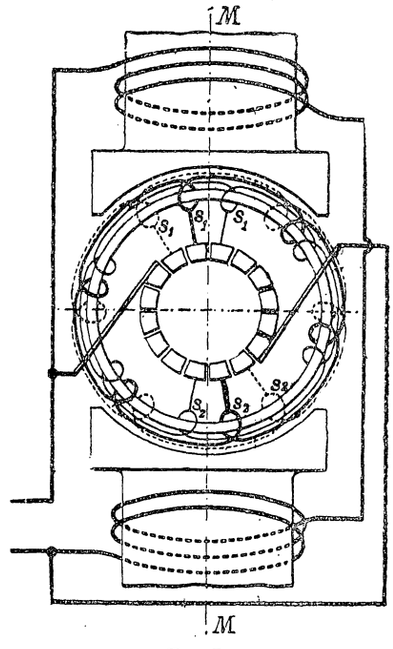

FIG. 3.

Déri now applies an electromotive force of about the value of that of the armature at 0deg. If, then, the brushes be placed at the corresponding point on the collector (the two electromotive forces being in opposite directions) there will be no current in the armature. There will be similar positions for various speeds of rotation, also at other points on the circumference. If, now, the brushes are displaced in any direction, the pressure of the applied

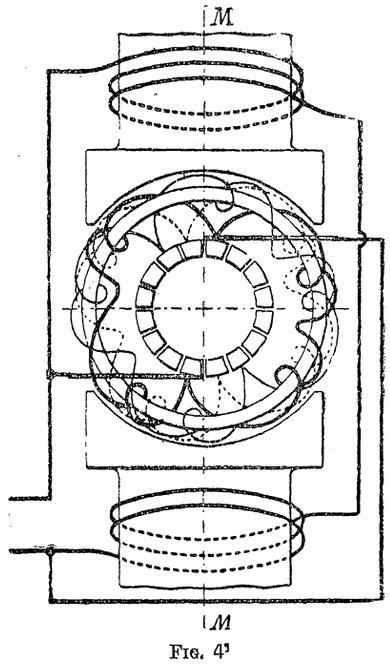

FIG. 4.

current will be higher than that of the coils, and a current will pass through the armature, which will produce a torque. Following up these considerations, the inventor has found the constructional requirements, which make the arrangement of the field in shunt not only possible but very advantageous. The fields are in a sense the primary portion of a transformer, whose secondary is the armature; and if the windings on the magnets and armature are so arranged that the voltage on the armature at M M, in consequence of the induction, is about equal to the voltage of the current caused by the field magnets—that is to the working pressure ($E = e\,n$)—then the motor becomes very easily capable of regulation.

The motor is started by displacing the brushes from the line M M gradually to such position (m), that the difference in pressure ($E - e\,n$) is sufficient to produce the required torque. As the speed increases, the electromotive force of the armature becomes greater, and the brushes are further displaced until the necessary difference in pressure takes place. If the brushes be displaced in the opposite sense, the armature rotates in the reverse direction, and the machine can be quite sparklessly reversed by gradually shifting the brushes through the centre line to the other side. It will be noticed that since any torque from nothing to its maximum can be obtained by shifting the brushes, the regulation can be obtained without any resistances, and reversals also take place without any special apparatus. It is also possible with a slow speed to get a large torque on the armature without great expenditure of energy, because the machine, in virtue of its transformer action, can develop a large current at small pressure.

The machine is to be regarded, says the inventor, as a transformer with two primary currents, the exciter current in the fields, and the working current in the armature; the latter current is opposed by the current induced in the armature by the fields. In the calculation of the energy used, the current in the armature (which is dependent on the difference $E - en$, and suffices to produce the necessary torque) must be multiplied, not by the pressure E of the working current, as in other electromotors, but by the difference ($E - en_0$).

The article points out that the regulation is somewhat analogous to the governing of engines by regulation of the expansion, in contradistinction to that hitherto used, which may be compared to

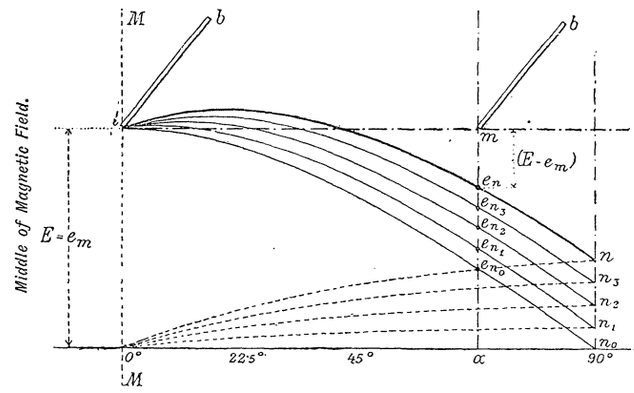

FIG. 5.

governing by the throttle valve, and this regulation may be accomplished by automatic shifting of the brushes, either with the speed or with the current strength; while for tramway work or electric railways a hand regulator, worked by the driver, would consist of a simple lever for shifting the brushes. Finally, the machine is said to be a very efficient one.

* This does not appear to apply to Figs. 1 and 2.—ED. *E.*

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS—TUESDAY, MARCH 21ST.

Edgware Road and Victoria Railway.

The Bill for the construction of an electric underground railway from the Brondesbury Station of the North London Railway to Victoria came before Sir John Kennaway's Committee of the House of Commons on Tuesday. Mr. Pembroke Stephens, Q.C., Mr. Worsley Taylor, Q.C., and Mr. Hume Williams appeared for the promoters, and the opponents of the Bill were represented as follows:—The Belgrave Mansions Company and their sub-lessees by Mr. Cripps, Q.C., and Mr. Lynden Bell; the Duke of Northumberland and Lord Iveagh by Mr. Littler, C.B., Q.C., and Mr. E. Page; the Duke of Westminster by Mr. Littler and the Hon. A. Lyttleton; the Authorities of St. George's Hospital by Mr. C. T. Giles; the London County Council by Mr. Freeman; the owners, &c., of houses in Grosvenor-place and Grosvenor-gardens, by Mr. Cripps, Q.C., Mr. Lynden Bell, and Mr. C. G. N. Trollope; owners, &c., of houses and property on or near the line of the proposed railway by Mr. E. Boyle and Mr. Terrell. There were several other petitioners against the Bill who did not appear by counsel.

Mr. PEMBROKE STEPHENS, in opening the case for the promotors described the course of the line, which he said followed a course direct as the flight of a crow for about 4½ miles and tapped a district abounding in every kind of traffic. Apart from the direct through traffic it afforded the most direct and convenient lateral communications with the existing railway systems, the London and North-Western, the Great Western, the

Hosted by Google

Metropolitan, and the southern lines at Victoria. The present difficulties of north and south communication were very great, and by this line the time now consumed in getting from Kilburn to Victoria would be reduced by at least one-third. Though the present Bill did not go before the Joint Committee of last year, it complied with the conditions laid down in their report and no doubt if it had been before them would have received the same stamp of approval as the other Bills did, and which were only recommended as instalments of the communications which were required. The capital for the line was £1,200,000 share capital, with £400,000 borrowing powers, which would allow a cost of over £350,000 a mile. The manner in which the line should pass by the side of Hyde Park had been arranged with, and assented to, by the Crown, and at Hyde Park-corner it would utilise a large waste space, which at present is only devoted to the purposes of a refuge. The learned counsel then dealt with the petitions against the Bill, the objections contained in which, he urged, were of a sentimental character, and said that the evidence he should call would show that the line was one which, if accompanied with reasonable protection for any of the interests which might conceive themselves to be affected, ought to be sanctioned by Parliament.

Mr. GREATHEAD, the engineer to the line, was then examined by Mr. WORSLEY TAYLOR, and described the objects and course of the line, which he said would be made with easy curves and gradients, and would, it was expected, receive a large traffic, not only from the streets which it traversed, but from the railways with which it would form communications. Land was scheduled at the north end of the line adjoining the London and North-Western Railway for a depôt for carriages, and other land was scheduled on the Paddington Basin for a generating station. That was a site suggested by Lord Brassey, when the original Central London line was before him, as being a very good place for a generating station, and on looking into it they found it was so. It was convenient, because it would enable them to get their coals cheaply, and enabled them to use condensing engines, which was rather an important matter. The depth of the line would be from 45 to 100 feet below the surface, and from the borings be believed they would be in the London clay throughout. He did not think there would be any vibration felt on the surface, and there would be no possibility of interfering in the slightest degree with the park or the growth of the trees in it.

A MEMBER of the COMMITTEE: Would the electrical action have any effect upon them?

The WITNESS: No, nor would there be any sensible vibration to affect them. Vibration certainly would not affect the trees, because on the Thames Embankment they grew very well quite close to the Metropolitan District Railway. There would be a two-minute service, and on the assumption that the trains were half full they would carry 27½ million passengers a year. That, at an average of 1¾d. per passenger would afford an ample return. The working expenses he estimated at £46,000.

Mr. H. W. PRIMROSE, C.S.I., Permanent Secretary to the Commissioners of Works and Public Buildings, said that they had considered whether the line would have any prejudicial effect upon the drainage and the vegetation of the trees, and considering the mode of construction and the great depth of the line below the surface, and the fact that it would be entirely in the London clay, they came to the conclusion that there was not the least fear on those grounds.

Mr. GREATHEAD was then cross-examined by Mr. LITTLER, who said that London seemed to be about to be scored like the skin of ribs of pork with lines north and south. He inquired as to the interest of the promoters of the Bill, but the witness stated that he could not give any information on that subject, having confined himself entirely to the engineering.

In cross-examination by Mr. FREEMAN, replying to a question as to whether they would not have very much more powerful locomotives and a very much stronger electric current than on the City and South London line, the witness stated that the pressure of the current would be the same. The locomotives would be a little more powerful, but very little more so than the last locomotives supplied to the City and South London line. The weight of the locomotives proposed to be used on this railway would be 15 tons; on the City and South London none were less than 10 tons, and some 13½ tons.

Replying to Mr. LYNDEN BELL, he said that he would pledge his professional reputation that he did not apprehend any subsidences or any vibration that could be felt.

The witness was cross-examined by Mr. WILLIAM TERRELL as to subsidence that was alleged to have taken place in connection with the City and South London line at Blackman-street, for which the Company had had to pay £900 in respect to repairs. That was owing to the works created for the purpose of a station, and not to a shaft that had been sunk some 260 feet. In reply to the Committee as to what was the life of the tubes used in the construction of the tunnel, he stated that he thought they would last for ages. It was impossible for corrosion to take place, as the tubes were encased on the outside in a shell of cement.

Does that preserve them better than the clay?—Yes. In the first instance, the iron is dipped into a composition which forms a rough coating of varnish, and then the cement on the outside of that prevents all action on the outside, so that it would remain perfectly fresh for a hundred years. I do not believe there would be a sign of any deterioration at all. On the inside it is intended to fill up the space in the same way, with concrete and cement, so that the whole tube will be perfectly protected both inside and out.

Does the action of the electricity have no effect?—No.

Mr. THOMAS BATE, a surveyor of Kilburn, was called to speak to the feeling of the residents of that district, which, he said, was distinctly in favour of the line, the present means of conveyance being very indirect and tedious. In his opinion it would enhance rather than depreciate the value of property, and would probably prevent the construction of a tramway which would be very objectionable. At the place where it was proposed to place the generating station there was not much property to injure, it consisting principally of laundries, Carter Paterson's warehouses, and so on.

WEDNESDAY, MARCH 22ND.

Mr. RICHARD SEXTON, a grocer living at Brondesbury, with business premises in the Edgware-road, said that for himself personally, and many of his neighbours, the line would prove a very useful means of communication. The Brondesbury district was rapidly increasing, and they really wanted a railway by means of which to reach the West End quickly.

Mr. JAMES ROBINSON, secretary to the Alexandra Hotel Company at Hyde Park Corner, said the line was favourably regarded by his Company.

Mr. J. F. SABINE, a bank manager at Brondesbury, said that the line would be welcomed by the people in the district. A large number of working men lived in the district, and the line would greatly convenience them by enabling them to get quickly and cheaply to and from their work.

Mr. HENRY HOADLEY, draper and warehouseman in the Buckingham Palace-road, employing 100 assistants, spoke as to the advantage it would be to the customers of his own and similar businesses in the neighbourhood to be able to travel by the line. He would certainly welcome it as a means of developing his business.

Mr. OLIVER C. ROBSON, engineer and surveyor to the Willesden Local Board, said there was a necessity for a better class of quick communication from Willesden and Kilburn and the West End. The population of the district had increased from 38,000 in 1883 to 68,000 in 1893, the whole of the district being of a residential character.

The CHAIRMAN said that it might be assumed that Kilburn was growing, that a great many people wanted to travel, and that the establishments and shops would very much like customers to be brought to them.

Mr. WORSLEY TAYLOR said they had a large number of witnesses, and the traffic was enormous, but he had some special working-class witnesses whom he would like to call.

Mr. S. T. CHANDLER, a compositor, living at Kilburn, and employed in Berwick-street, Oxford-street; Mr. SAMUEL CRANE, a carpenter, living at Rye-lane, Peckham, but employed at Kilburn, to and from which he journeyed daily, then gave evidence in favour of the line.

Superintendent CHARLES W. SHEPPARD produced statistics of traffic at Grosvenor-place on March 16th (weather showery) between 8 a.m. and 12 midnight, showing 12,717 foot-passengers and 10,293 vehicles, out of which 2,474 were omnibuses.

Superintendent COLE produced similar returns.

Mr. EDWARD LAFONT HEATLEY, merchant of Gracechurch-street, one of the promoters, and one of the Directors, named in the Bill, gave evidence as to the circumstances attending its promotion, stating that the Directors were responsible for the deposit, and no one else had any control over the Bill. They were satisfied as to the commercial prospects of the line, and he would be prepared to recommend his friends to invest in the undertaking. There was no lack of capital. The only thing was that there was lack of confidence as to what were the best investments, and at such times in his experience it was such undertakings as these that people would invest in. Sir Frederick Johnstone was also a Director, but was too unwell to attend to give evidence. In cross-examination by Mr. Littler, he said that Messrs. Fowler, the solicitors, introduced him to the scheme, and he proposed to take a considerable stake in it, though to what extent he was not at present prepared to say. He had not contributed to the preliminary expenses, that part of the matter having been arranged by the solicitors. In further cross-examination by Mr. Cripps, the witness stated that the amount of the deposit was £47,000 for which a security had been provided to the bank, and for repayment of which he and the other Directors were responsible. He and those associated with him had found very large sums of money for their own enterprises abroad, sometimes as much as half a million of money, and therefore he was well acquainted with a number of people in the financial world, but he had never been connected with the financing of a railway project in England.

Sir DOUGLAS FOX, joint engineer with Mr. Greathead to the scheme, said that of all the underground railways he thought this route presented the fewest difficulties. There would be no injury to St. George's Hospital from noise or vibration either from the construction or the working of the line. The estimates for the work were sufficient, but they thought it necessary to provide first of all for the cost of an electrical installation and various subways which were not technically included in the estimates. Then there would be the whole of the engineering and the other services connected with the carrying out of the works, but they had adopted the precedent of the Great Northern and City Railway which was sanctioned by Parliament last year, and the proportion would be about the same. The estimate was £1,200,000, and the share capital was fixed at a million and a-half. The borrowing powers would supply the rolling stock and things of that sort.

Mr. A. T. WALMISLEY, an engineer who had been engaged for owners of property in connection with the City and South London line gave evidence that although he hoped to find some damage there he had not been able to do so, and there was no complaint from the tenants of property overhead.

Mr. H. A. HUNT, surveyor to Lord Cadogan, the Dean and Chapter of Westminster, &c., gave evidence as to the land estimates, which amounted to £8,000. As representing the Paddington Trustees, he said they hailed the line with great satisfaction, because they had never been able to get proper access to their estate.

This closed the case for the promoters, and

Mr. CRIPPS addressed the Committee on behalf of the owners of Belgrave-mansions and residents in Grosvenor-place and Grosvenor-gardens. He said they were satisfied that there was no intention to interfere in any way with the surface of Lower Grosvenor-gardens, but their general objection to the proposal was, first, that no public case had been

Hosted by Google

shown in its favour, and that there was no reasonable probability if the Bill were granted that the line would ever be made. Their special objection, however, was to the proposed station at Hyde Park-corner, which, bringing at that point a large number of passengers, would be not only a great inconvenience, but a very serious nuisance to the residents of Grosvenor-place. When the Hyde Park-corner improvements were carried out £11,800 was privately subscribed towards them in order that the open space might be kept and the traffic properly regulated, and the object for which that money was subscribed would be entirely defeated if the proposed station were placed there. He criticised the financial basis of the scheme, and said that, considered as an ordinary business of a commercial nature, it was ridiculous, it being altogether unlikely that the money would be subscribed. The opponents represented a much larger public interest and a more substantial interest, for the line was really of a bogus character, both as regards its convenience and its future prospects.

Sir JOSEPH PEASE, M.P., residing at 44, Grosvenor-gardens, was then examined in opposition to the Bill, and said that although the promoters did not at present propose to interfere with the surface of Grosvenor-gardens, he felt sure they would do so hereafter. His own experience in the railway world led him to believe that wherever a railway company got its feet in it would get its head and shoulders through afterwards. The line would greatly depreciate his property, and destroy its amenites ; in fact he would not have bought his house if he had not thought he was free from a railway of that description close under its foundations. The project of the line had already depreciated property in the neighbourhood, though he admitted that the objection was a sentimental one to a certain extent. The whole of the residents in Grosvenor-gardens and Grosvenor-place were opposed to the scheme, and he did not consider that the line was wanted, the traffic being more east and west than north and south. If a large number of people were to be landed at Hyde Park-corner, it would be a great detriment to all the houses, and especially to the hospital. It would interfere with the traffic arrangements, with the crossing arrangements, and the general user of the public. The whole place was laid out for picturesque purposes, and was perhaps one of the greatest metropolitan improvements that had been carried out for a long time. But if the Company once got permission to make a staircase down to the station there, they would come another year and want something more.

Cross-examined by Mr. PEMBROKE STEPHENS, Sir JOSEPH said he much feared that there would be vibration. He already felt the vibration of the District Railway, which was much farther off. In his opinion Parliament would be going far beyond its ordinary scope to give to two or three speculators a power which would damage the value of property of over a mile of good houses.

Mr. E. N. SHACKLE, surveyor and estate agent, also testified that the construction of the line would lead to the depreciation of such residential property as that at Grosvenor-place and Grosvenor-gardens. In the case of the Central London line, he had met with failures of negotiations because the Company had got their powers and had not used them, and Hereford-gardens had certainly depreciated in value since the Central London Bill was passed. The station at Hyde Park-corner would add to the dangerous character of that crossing, and the feeling of the neighbourhood was unanimously against the line. He estimated that the depreciation of property in Grosvenor-place would amount to 25 per cent., which would mean £250,000 roughly.

The Committee then adjourned.

THURSDAY, MARCH 23RD.

Mr. HENRY LOFTS, estate and house agent and surveyor, of Mount-street, Berkeley-square, said that he had had to deal with property in Grosvenor-place. The capital value of four of the mansions with which he had dealt would be £180,000, but if the line were passed the depreciation, he estimated, would be quite 25 per cent. When he had a short time ago to deal with No. 4 for the Duke of Grafton, he looked upon it that his property was considerably improved by the open space which had been made by subscription from various owners in the neighbourhood. People had a prejudice against a railway coming near them, because it was the thin end of the wedge, and they did not know how it might be enlarged or the traffic increased. He had recently an instance of a property on the underground railway where he had to advise the purchaser, and told her that the only drawback was the proximity of the railway, and that it caused vibration. The lady had a cup and saucer put on the floor of the dining room, and said she did not object to the vibration ; but a few months afterwards she complained that the vibration had become most serious on account of the weight of the engines having been doubled. In cross-examination by Mr. Pembroke Stephens the witness said that it was not simply prejudice against railways which would lead to the depreciation ; but the station would bring around it a number of idlers, people who sold flowers and matches and newspapers and that kind of thing.

Mr. FREEMAN addressed the Committee for the London County Council, but intimated that he should call no evidence. The Council, he said, had thoroughly impartially considered this particular Bill, but they considered it would be injurious to the metropolis, and therefore, in the public interest they asked the Committee to reject it. They feel that it was not a *bona fide* line intended to be made. The Central London line, of which Mr. Greathead was also the engineer, had not yet been commenced, owing to difficulties connected with the City, but he contended that there was no financial support behind this line, and that at any rate before it was authorised they were entitled to see a substantial beginning made with the Central London line. At present this was only an engineers' and solicitors' line, and stood in an entirely different position from the Central London and Great Northern and City Lines, where there was a mass of substantial evidence, and persons of weight came forward who said they were prepared to carry out the schemes. When a Bill came before Parliament with so shadowy a foundation, so unknown a promotion, and so unreal a backing, the County Council, as responsible for the control of the metropolis, felt that they entitled to ask Parliament to withhold their approval to it. But they were specially objected to the interference with the open space and roadway at Hyde Park-corner, which was created and preserved for the assistance and protection of the general public, towards which the Metropolitan Board of Works contributed £20,000. The Council thought it their duty, on public grounds, to strenuously resist the making of the line at all, and they especially asked the Committee not to do away with the good effect of the improvement of 1883 by sanctioning at Hyde Park-corner something which must be a nuisance, and which would shortly become an eyesore to the place.

Alderman GEORGE FAUDEL PHILLIPS was then called in support of the opposition of the Duke of Westminster. He said he resided at 52, Grosvenor-gardens. The Underground Railway from Victoria to Sloane-square passed under his garden, and he fancied under the corner of his house. He had spent a large sum of money in putting up iron girders with a view of stopping some of the vibration and oscillation, and though it had done some slight amount of good, yet that very morning he was awakened at six o'clock by the fire-guard rattling in the grate, caused by the passage of the workmen's train. If anyone were ill in the house that would be very serious, and he believed that if another railway were to come, his house would be more of a liability than an asset, as he would not be able to live in it, and was perfectly certain that he could not sell it. In cross-examination he admitted that he knew nothing of the present scheme, how near it would be, how deep it would be, or how much it would affect his property.

The Hon. W. F. D. SMITH, M.P., who lived with his mother, Lady Hambledon, at 3, Grosvenor-place, also opposed the Bill. His father was one of the subscribers to the improvement of the open space between Hyde Park-corner and Grosvenor-place. Both he and his mother objected to the scheme on the ground that it would seriously depreciate the value of their house. It was proposed to place both the entrance to the station and public lavatories for men and women on the open space, and that would be very objectionable to the inhabitants.

Mr. ALFRED GILES, civil engineer, who for many years was M.P. for Southampton, said that he resided at 21, Grosvenor-place, being lessee under the Duke of Westminster. He considered that there was no necessity for the line and was doubtful how long it might be kept hanging over the heads of the residents in Grosvenor-place in reference to the subscription of the capital as it was entirely a speculative scheme.

Mr. EUSTACE BALFOUR, surveyor to the Duke of Westminster, agreed with previous witnesses that the scheme was a speculative one, and seemed to be an isolated effort to deal with the question of subterranean traffic. While the Duke of Westminster would not object to any great public improvement, he objected to this scheme on the ground that it seemed to be ill-considered, that it was very elementary in its character, that it was not part of any broad metropolitan scheme for subterranean traffic, that the engineering details did not seem to have been sufficiently considered, and that it would be a pity to take up ground of that kind, and possibly injure the houses in the neighbourhood in various ways unless it formed part of some very broad scheme for the benefit of London as a whole. It would be a serious nuisance to the open space in front of St. George's Hospital, partly from the gathering together of a very large traffic, and partly from the fact that there must be some structure above the ground, and however quietly that was done, it must be an eyesore. The duke and his trustees subscribed £3,000 towards that open space, and it would be extremely unfair to them that that money should be thrown away.

Lieut.-Colonel R. H. ATKINSON was called on behalf of the Duke of Northumberland and Lord Iveagh, and said that he was private secretary to Lord Iveagh, who subscribed to the Wellington-place improvement. Nos. 4 and 5, Grosvenor-place were lighted by electricity, which was generated by engines in the cellars of the premises, and the line would come within a few feet of those cellars. He was told by those who had technical knowledge, which he himself did not possess, that the electric current of the railway would seriously affect the storage power of the accumulators placed in the cellars.

Mr. DANIEL CUBITT NICHOLS, architect and surveyor, said that the cellars of the houses in Grosvenor-place were 11ft. below the roadway, and extended within the limits of deviation.

Mr. RICHARD HASSARD, civil engineer, said the railway could not be constructed without doing damage to the houses in Grosvenor-place, and after it had been made further damage would ensue from vibration.

Mr. EDWARD SEATON, also a civil engineer, who was engaged in the construction of the Inner Circle completion, also expressed the opinion that there would be difficulties in the constuction of the line, which would be dangerous to the house property, and

Mr. JOHNSON, foreman to Warner and Sons, who built the houses in Grosvenor-place, proved that they had to go down as deep as 40ft. to reach the London clay before they could make the foundations.

Mr. THOMAS P. PICK, surgeon of St. George's Hospital, expressed the view that the placing of the station opposite to the institution would be detrimental, and that the patients would suffer from noise and vibration. In the operating rooms electric apparatus was used, and if that were interfered with by the railway it would be prejudicial to the patients undergoing the operations. They might find the electrical apparatus fail in the middle of an operation.

Mr. W. H. BENNETT, also a surgeon at St. George's Hospital, gave similar evidence.

Mr. GILES then addressed the Committee for the hospital authorities, contending that the station at Hyde Park-corner would be a serious nuisance, and on the question of electrical disturbance as affecting the instruments in use at the hospital appealed to the evidence given before the Committee on the Clapham Junction and Paddington Bill.

Hosted by Google

The case of owners, lessees, and occupiers of houses and property on or near the line of proposed railway was then entered upon, Mr. ARTHUR S. M. BLUNDELL, civil engineer, and Lord STANLEY of ALDERLEY giving evidence on their behalf. Lord Stanley thought the line was not required, and that it would injure his property to the extent of £3,000.

Mr. BOYLE then addressed the Committee in support of the case of these petitioners, urging that there was no public want for the railway, and that not 10 per cent. of the traffic found its way north and south. Facts were stronger than Mr. Greathead's ideas; his ideas had proved to be wrong in the past, and they had no reason to imagine that they would be right in the future. The City and South London line had not been a success, paying only 6s. 3d. on its ordinary shares; but even if it paid £6 there would be no justification for such a line as the present, which was, as he termed it, a cross-country line. If the scheme was a necessary one, and the inhabitants were to suffer the consequent damage, he asked that it hould not be in the hands of a speculative promoter—another Oxford-street scheme, only worse—to be hawked about the City in the hope of getting somebody foolish enough to take it up, but which could only be the means of ruining all who were ignorant enough to have anything to do with it.

Mr. LITTLER also addressing the Committee on behalf of the Duke of Westminster, the Duke of Northumberland, and Lord Iveagh, said that east and west communications were the only ones which would pay, and that this line was chosen, not by anyone on the line of route or by anyone who wanted to travel by it, but by some highly estimable solicitors in Westminster who thought it would be a good thing to have the line. He commented upon the absence from the witness-box of the promoters other than Mr. Heatley. Nothing was worse than to have a speculative scheme hanging over property, with extension after extension of time, which was always the result of speculative schemes, and he respectfully protested against either lawyers or engineers coming for speculative purposes and interfering with property of such vast value as that in Grosvenor-gardens and Grosvenor-place.

At the close of Mr. Littler's speech the Committee adjourned.

FRIDAY, MARCH 24TH.

Mr. PEMBROKE STEPHENS replied at some length to the arguments of the counsel for the opposition, urging that the promotion of the line was perfectly *bonâ fide*, and that only illness prevented them from having the advantage of Sir Frederick Johnstone's evidence, while the damage to the Hospital and other property, of which so much had been made, would not be realised.

The Committee then consulted in private for about a quarter of an hour, and on the re-admission of the public,

The CHAIRMAN said they had given the scheme the most anxious and careful consideration, but they felt bound to come to the conclusion that the preamble had not been proved.

The Bill was therefore rejected.

Hampstead, St. Pancras, and Charing Cross Railway.

On the consideration of the Hampstead, St. Pancras, and Charing-cross Railway Bill by the House of Commons on Friday last the following clause was, on the motion of Mr. T. H. BOLTON, substituted for clause 81 in the Bill as reported to the House:—

"The Company, at all times after the opening of the railway for public traffic, shall, and they are hereby required to, run at least three trains which shall call at every station each way every morning in the week and every evening in the week (Sundays, Christmas Day, Good Friday, and Bank holidays excepted) at such hours, not being later than seven in the morning or earlier than six in the evening respectively, as the Company think most convenient for artisans, mechanics, and daily labourers, at fares not exceeding one penny for each journey. Provided that in case of any complaint made to the Board of Trade of the hours appointed by the Company for the running of such trains, the Board shall have power to fix and regulate the same from time to time. Provided, also, that the liability of the Company under any claim to compensation for injury or otherwise in respect of each passenger travelling by such trains shall be limited to a sum not exceeding £100."

The Bill as amended was ordered for third reading.

Royal Assent.

The following Bill has received Royal Assent:—The Baker-street and Waterloo Railway.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March 17*, 1893.

Prof. Elisha Gray's Telautograph.—On Tuesday, March 21st, a private exhibition will be given to the Press, both in New York and Chicago, of the workings of Prof. Elisha Gray's telautograph, which, as might be inferred from the name, is a means of transmitting over electrical wires autographic communications, which are reproduced at the further end in facsimile. The public has already heard something of this system, but the knowledge that has heretofore leaked out has been somewhat vague and uncertain. The writer has just had a private view of the operation of this instrument, and can state from observation that the reproduction is an exact facsimile of the original, and that the sender's signature can be recognised as readily as can a speaker's voice over the telephone. The transmitting instrument consists of an ordinary lead pencil, to which are attached two strings at right angles to each other, which convert the motion of the transcribing pencil into two components at right angles to each other, each modifying an electric circuit in exact proportion to its component. The paper upon which the transcription is made rests upon a metallic plate normally out of contact with the circuit, but which is brought into contact by means of a slight pressure of the pencil. When the transmitting and receiving instruments are placed side by side their operation reminds one most forcibly of the operation of the two ends of a pantograph, which, in fact, they resemble most closely, the connection between the sending and receiving stylus, however, being electrical instead of mechanical as in the pantograph. It is claimed that some 35 words per minute can be transmitted in this way to the same distance to which telegraphic messages can be sent without the assistance of relays, and that this distance may be increased as far as desired by the usual relay methods adopted in telegraphy. In fact, as to speed of transmission, it is claimed to be limited only by the ability of the writer to transcribe the words with the lead pencil or pen. It is, however, manifest that this is not strictly accurate, as one cannot operate the sender as rapidly as he could write the same words with a pencil unattached to the controlling strings. The speed, however, will compare favourably with that of transmission by means of Morse signals by hand. The receiver transcribes the message by means of a glass ink tube or pen similar to the receiving stylus employed in the siphon recorder in ocean cable telegraphy, this motion being the resultant of the rectilinear motions transmitted. Figures and outline drawings are also reproduced with great fidelity. In the original system invented by Gray four wires were employed between the two instruments, two circuits being required. The obvious simplification, however, of employing but a single return for these two circuits has more recently been adopted, so that now but three wires instead of four are employed. Prof. Elisha Gray is well known in electrical circles, and is Chairman of the Advisory Council of the World's Congress of Electricians, to be held at Chicago, at the time of the Exposition. He will also be remembered as having been one of the claimants for the invention of the speaking telephone, his own device for the transmission of speech having been exhibited at the Centennial Exposition in 1876, at the same time that Bell first publicly exhibited his invention. It is proposed to connect telautograph subscribers together through a central exchange in a manner exactly similar in principle to that with which we are so familiar in telephony. When one subscriber, A, wishes to communicate with another, B, both connected through the same exchange, A merely writes on the paper "A to B," when the operator makes the connection, and the two are in communication.

The Bell Telephone Patent.—A great deal of interest is being manifested just now by the public at large in the telephone situation, as the basic patent granted to Bell in 1876 has expired, and the art is now open in this country to the public. This first patent is limited to the use of a parchment diaphragm, and it is claimed by the Bell Company that it does not cover the use of the all-metallic diaphragm, which was given to them in a subsequent patent in January of the next year. They, therefore, claim that the art of telephony will not be open to the public until 1894. There is, however, at the present time talk of new companies to be organised for telephonic work in competition with the existing Company, but these the Bell Company is discouraging by every means in its power, among which are claims of fundamental patents in switchboards, transmitters, and other accessories, which, however, are not likely to frighten anyone who seriously contemplates entering into the business.

The Chicago Exhibition.—Mr. Frederick Sargent, so long at the head of the mechanical and electrical departments of the World's Fair, has recently resigned. It is understood that a conflict in authority, which he felt seriously crippled his work, was the cause. The duties thus laid down by Mr. Sargent have been assumed by Mr. R. H. Pierce, Mr. Sargent's former assistant.

Hosted by Google

THE BATTLE OF THE "TICKERS."

As will be seen elsewhere in our columns, during this week a company called "The Printing Telegraph and Construction Company of the Agence Havas (Limited)" has appealed to the British public for a capital of £115,000 to enable, amongst other things, a system to be carried out of electrically transmitting to and printing news in the offices of subscribers in France. The experience obtained in this country during the last twenty years in connection with similar systems cannot fail to throw light upon the amount of success likely to be obtained in this new departure across the Channel.

The first point that strikes a reader of the prospectus of the Company named is "Why should the public here be appealed to for the money required?" If the credit of the Agence Havas is so high, should it not be able to secure the amount in question in France? There must be a reason for money being sought here for a purely French undertaking, and it is possible that this may be found in the fact that the Agence Havas have been severely affected—their shares have fallen from about 600fr. to 200fr.—by the competition of the Agence Dalziel, which has also a concession, prior to that of the Agence Havas, from the French Government for electrical news printers, and is now engaged in constructing its system and obtaining subscribers, the instrument used being that known in this country as the Exchange Company's Column Printer.

It should also be pointed out that two previous unsuccessful attempts have been made to introduce news-recording instruments into France, the last having been made some twelve years ago under the auspices of the Agence Havas itself. It may, however, be admitted that *prima facie* in some respects there is a better field in Paris than in London, where the rapidly-recurring editions of the afternoon and evening papers make news instruments less necessary; but the prospectus estimate of 1,000 subscribers for this particular Company's instruments in Paris, according to all experience here, is not likely to be attained for a number of years, if ever.

By internal evidence the prospectus before us has not been drawn up by anyone acquainted with the working of these instruments. The gross receipts to the new Company are given as £27,600, with the estimate of a dividend of 15 to 20 per cent. Taking an average of 17½ per cent., which would absorb £20,125, there would be left £7,475 for working and maintenance of instruments, royalties to the French Government, and general expenses.

To commence with, there is the royalty of £1 per instrument, the charge made by the Government for maintaining a metallic circuit in place of the single wire used here, the heavy cost of paper in France, and other items. In our view even double the sum named would not nearly suffice for these expenses.

There are several points in the prospectus which ought to give pause to intending subscribers. For instance, under the concession "The French Government are entitled to purchase at a valuation, at any time, at a price *exclusive of any value for the patent*" (for which, and certain other minor considerations, no less than £75,000 is to be paid), "the whole of the plant, property, and machines of the Company in Paris and its environs." Again, after thirty-five years the machines, wires, plant, &c., &c., which are to be paid for by the Company, are to become the property of the Agence Havas, which is also to receive £8,850 in fully paid shares of the Company and 54 per cent. of the gross receipts from subscribers. This large percentage does not include up-keep, installation, wages of operators, taxes or other administrative expenses. It is, therefore, reasonable to describe this undertaking as an Agence Havas Relief Company.

It is claimed that the instrument to be used in Paris is faster than any column printer now in use, and that it costs 30 per cent. less; but there does not appear to be much in the claim, in view of the fact that a French paper, after inspecting both the Wright instrument (adopted by this Company) and that best known here as the Column Printer, stated that there appeared to be little difference, except that one was driven by a weight and the other by an electric motor, and the fact remains that the "Exchange" type printer was patented some time before the Wright instrument.

Finally there remains a sum of only £40,000 for working capital, which is certainly insufficient, seeing that the Company have to purchase the instruments and apparatus, to pay the cost to the French Government of installing the wires, &c., even should the reports current in the City as to the high percentage of commission offered to underwriters prove unfounded.

BOOKS, &c., RECEIVED.

"Die Berechnung Elektrischer Leitungsnetze." By J. Herzog and C. P. Feldmann. (Berlin: J. Springer.) 350 pp., 8vo.

"Anordnung und Bemessung Elektrischer Leitung." By C. Hochenegg. (Berlin: J. Springer.) 180 pp., 8vo.

CORRESPONDENCE.

THE REVIEWING OF NEW BOOKS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: An author has not much protection against the irresponsible reviewer, and generally it is not considered etiquette to question the latter's dictum; but when a palpably unjust notice appears in what is generally considered the leading electrical paper, it is time to protest against the carelessness of the reviewer. This, Sir, is my excuse for writing to you, and I hope you will do me the justice to consider my claims.

Your reviewer (in last week's issue) starts with the binding of my book, surely a point to be considered last of all. He might have guessed that the work when complete would be issued as one volume. When such is the case, it is usual to issue the parts in paper covers. He next attacks the table of conductors and insulators; surely an engineering student would wish to know the comparative conducting powers of metals. The difference between conductance, resistance, conductivity, and resistivity, cannot be too soon impressed on the student. How many people carelessly use the term *conductivity* as the reciprocal of *resistance*. Anent this, I would ask you to refer to my enclosed article.

An engineering student is not a student of pure science, and therefore hand-rules, *e.g.*, are admissible. One of my students originated a hand-rule for finding the + direction round the magnetic field of a straight current-carrying conductor. This, obviously, is a fundamental rule, and it was characterised as "excellent" by one of our greatest electricians, whose name however, I am not at liberty to publish. In this rule, the hand can only be placed with the thumb in the direction of the current, and the fingers in the direction of the field; and it is clearly convenient that other hand-rules should be made to agree with this. I enclose an article of mine on this subject.

There are two *real* faulty points which your reviewer mentions, and for which I am grateful. In all my published works I have written for the beginner, and though they do not strike very new ground, I have been led to think that they will be found original in arrangement and treatment. The despised elementary book is quite as much wanted as the advanced treatise; else how are we to keep up our supply of electricians, and how are the public to get initiated?—Yours, &c., W. PERREN MAYCOCK, M.I.E.E.

96, George-street, Croydon, March 24, 1893.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Kindly allow me to make a few remarks upon Mr. Maycock's strictures on my review of his book. In the first place, the phrases, "irresponsible reviewer" and "leading electrical paper" involve, as Mr. Maycock uses them, a contradiction in terms. A reviewer who writes for any paper of standing, and especially for a leading paper, cannot be irresponsible. Indeed, the responsibility connected with reviewing is very complicated; there is not only the responsibility to the editor, there are also grave responsibilities to the author and to the public. One feels these very much in dealing with a book of the class to which Mr. Maycock's letter especially refers. Justice is one's first and last consideration; and this sometimes leads one reluctantly to write those unfavourable reviews of which Mr. Maycock is complaining. Reviewers, of course, are human—very human; and they are as liable to err as authors are. Were one, however, to give a roseate hue to the review where blacker lines were needed, the public would soon discover that the review column was unreliable and useless reading. The review of Mr. Maycock's book was only written after mature consideration.—I am, Sir, &c.,

London, March 28, 1893. THE REVIEWER.

[Mr. Maycock is fully entitled to protest, and our reviewer, who has, by-the-bye, our full approval, to reply. Many people, Mr. Maycock observes, "carelessly use the term *conductivity* as the reciprocal of *resistance*." But they do so in good company. In the lecture delivered at the Institution of Civil Engineers on March 3, 1883, by Sir William Thomson, he said, "We want

Hosted by Google

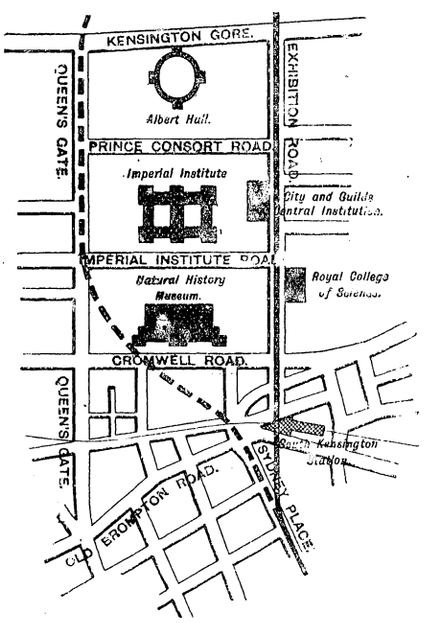
a name for the reciprocal of resistance. We have the name 'conductivity,' but we want a name for the unit of conductivity," and he then tentatively suggested the "mho." The well-known "hand-rule" in which the thumb indicates the direction of the north pole as well as the deflection of the needle, while the fingers point in the direction of the current, was taught at Cambridge by Prof. Garnett, while demonstrator to Clerk Maxwell in 1877, and is, therefore, of considerably older standing than the whole industry of electrical engineering. And yet Mr. Maycock says that it is clearly convenient that other hand-rules should be made to agree with his! We cannot follow the connection between the deluge of elementary books and "our supply of electricians." Must a new book come out for each hundred infatuated lads who rush into electrical work because it is supposed to be "the coming thing?"—Ed. *E.*]

CLAPHAM JUNCTION AND PADDINGTON RAILWAY.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your issue of the 24th March, p. 597, you reproduce from "a plan issued by the promotors" the "projected route of" the proposed "railway," with a deviation "as proposed by Professor Ayrton," shown by a dotted line.

I shall be much obliged if you would will be so good as to allow the enclosed plan to appear in your next issue, as it more



accurately gives the two routes. The sketch plan that you have followed, was, when drawn last year, only intended as a general indication of the line and position of the stations, and is not accurate enough in detail to give an idea of the merits of the two routes.

Your readers will judge for themselves of the material difference between being able to prove an "effective" line in one case and the other, especially in the case of the use of cable traction which was included in the Bill, but an important difference which led the projectors to reject "Professor Ayrton's route" (which, by the way, we had fully considered), was that it would have necessitated the acquisition of private property, both freehold and leasehold, the value of which must have added considerably more than £100,000 to the estimates. —Yours etc., C. E. Webber.

Portland House, E.C., March 27, 1893.

[The above diagram has been engraved from General Webber's plan so far as it relates to the streets and to the projected route of the line as shown in black. He had indicated a dotted line passing with a radius of about six chains under Thurloe-place into Cromwell-road, and turning with a similar radius up Queen's Gate. As this hardly represented the proposed deviation, we have submitted the plan to Prof. Ayrton, who has laid down a route, as shown by the dotted line. The plan sent to us by General Webber is, however, inaccurate in several particulars. The end of South Kensington Station, for example, should be in a line with the west side of Sydney Place. Prof. Ayrton's route runs for the most part under a mews in passing from Sydney Place to Cromwell-road, and below only one house in Cromwell-road. As this proposed route is not contemplated in the present Bill, further discussion of the matter is unnecessary.—Ed. *E.*].

PLUMBAGO-CLAY RESISTANCES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have read with interest your editorials, relative to resistances made of plumbago and clay, in your issue of February 24th, 1893. I have been experimenting off and on for some years in this direction, and have made some of these resistances, which have proved to be very satisfactory indeed. I have also used them as you suggested, in electrical supply circuits for ringing electric bells, and found them to give most satisfactory results. In addition to this, I have used them in connection with electrical apparatus on circuits of very high voltage; moreover, in experimental work, I have found them of great advantage on voltages running up to 10,000 or 15,000. I frequently use other substances in addition to the plumbago and clay, and in some cases have found that the temperature coefficient was very small indeed. To illustrate how tough some of these have been, I might say that with 1,000 volts I have heated a piece four inches long to a uniform red heat without any apparent disintegration of the carbon pencil. I believe in the future, resistances of this kind will be much more extensively used than they are at present.—Yours, &c., Henry W. Fisher, Electrician,
Standard Underground Cable Company.

Pittsburg, Pa., March 14, 1893.

MAGNETIC EFFECTS FROM THE ELECTRIC RAILWAY.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Your editorial remarks may convey the impression that I was first to observe the particular character of the magnetic effects of the Electric Railway, but the credit of these magnetic observations is entirely due to Prof. Ewing, for, previous to his investigations, I had only interested myself with the earth currents.—Yours, &c., F. H. Glew.

Clapham Road, London, S.W., March 27, 1893.

THE BROWN SINGLE-PHASE ALTERNATE-CURRENT MOTOR.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Since the appearance of my article on single-phase alternate-current motors, some little correspondence on the subject has arisen, to which I now beg to submit the following answer. I should have written before this, but I have been for some time absent from Baden, and I also wish to give time for the other side of the question to be fully stated before replying.

On reading the various letters, I was really amused to notice how that, after the publication of the particulars of my motor, everyone has suddenly discovered that he invented it himself long ago. I can only remark, and I imagine that most readers of the correspondence will agree with me, that had any of these motors come within measurable distance of a solution of the problem they would long ere this have come into general use. Prof. Elihu Thomson claims to have produced such a motor in November, 1888, and MM. Hutin and Leblanc had as early as May, 1891, so complete an insight into the underlying principles of the problem as to write an elaborate mathematical article upon the subject. In neither of these cases, or in that of Mr. Tesla, who also worked in the same direction, was there any lack of capital to assist in bringing the motors before the public; yet although in each case ample time has elapsed, the machines have not come into use in practice, in spite of the fact that there has always been a great demand for a self-starting alternate-current motor

Hosted by Google

without a commutator. I have no wish to underestimate the importance of the work done by Prof. Thomson, Mr. Tesla, and other early workers in the field, but I would point out that certain points in their machines were inherently defective, and that it was only by remedying these that I have succeeded in producing a practical single-phase motor. As some further elucidation seems to be necessary, I will describe more exactly the points in which my motor differs from the earlier ones, and to which I attribute its success.

From the published figures and descriptions of the motors of Thomson, Tesla, and Leblanc, it is apparent that the arrangement and winding of the magnetic circuit, both in the fixed and rotating parts is suitable only for synchronous working, the number of poles and windings being the same in both. It will also be noted that all the above-mentioned motors have very sharply-projecting poles, so that the magnetic resistance varies according to the position of the rotating part with regard to the fixed. The result of this will be that the former will have certain positions in which it will tend to place itself, and only when in these positions can currents be properly induced in it. Such a motor can only give power when running synchronously, and cannot be started with a two-phase current, even if of exactly 90deg. phase difference as produced from a two-phase machine except, perhaps, with very low periodicities, and even then without appreciable torque. In fact, in most cases the motor will only run if first brought up to almost synchronous running by some external means.

In the motor described in my article, on the other hand, there is no correspondence whatever between the winding or form of the magnetic circuit in the outer inducing and inner induced parts. On the contrary, they are, and must be, completely different from one another. It will also be observed that there are no sharply-projecting poles, but that the inducing winding is carried in a large number of holes which are uniformly distributed over the whole surface of the iron. The short-circuited induced winding is also carried in holes uniformly distributed over the surface of the rotating part. The numbers of holes in the induced and inducing parts respectively must have no common factor. The result of this arrangement is that when a single phase current is sent through the outer or inducing winding, the inner part has no tendency to place itself in any particular position. If, in such a system, a second current is employed, as more exactly described by me in my article, having a difference of phase from the first, a turning moment is produced, the motor is started, and on reaching a certain speed this second current is cut out. The motor then runs up to a speed corresponding to its load, and only when running light will the speed approach synchronism. When loaded the speed of the rotating part sinks so far below synchronism that the current produced by this difference of speed gives the necessary torque. The extent of this drop depends on the form of the rotating part, as explained in my former article. With regard to speed and armature current, the motor is, therefore, exactly analagous to a direct-current, shunt-wound motor. The bedding of the winding in holes, as so often explained, is for the purpose of reducing the current required for the excitation and thus securing a high-plant efficiency. I would also point out that the weight efficiency of these motors is entirely dependent upon the proper choice of the various proportions. By suitable design remarkably favourable results may be obtained. Thus I have now several 10-H.P. motors at work giving this power at the low speed of 800 revolutions, with a weight of only 500 kilogrammes and the heating is practically *nil*. As a matter of fact, one of these has been at work (in a saw-mill at Ragaz) day after day giving over 15 H.P. with moderate heating and has even been braked to 20 H.P. without pulling it up. Preliminary experiments show that the motor has a commercial efficiency of 88 to 90 per cent., the apparent watts being only about 12 per cent. in excess of the real watts. I must not omit to mention that this motor has no sliding contacts, and had sufficient starting torque to set in motion a line of shafting.

With regard to the letter from Herr Arnold, which appeared in several technical journals, I can simply state that the development of my motor dates from 1891, as stated in my article, and that after definitely settling all details I also applied for patents. Unfortunately, I was sufficiently incautious to explain my improvements to various interested people, so that the secret more or less leaked out. In his letter Herr Arnold attempts to treat the motor as a mere copy of those of Tesla and Thomson—whether from ignorance or design I am unable to say.

With regard to the letter of MM. Hutin and Leblanc, claiming priority in the invention of the motor in its essential principles, I would only say that from an examination of the French patent specification No. 204,456 it may be seen to be a two-phase motor of the Tesla type, the two phases being produced either from a special generator or by splitting the original current by means of a condenser which is always kept in circuit. Judging from my own experience, I must rather doubt if this motor would start even with two-phase current of 90°-phase difference, as the whole design points to synchronous working.

Referring to the American patent No. 487,633 mentioned by Prof. Elihu Thomson, I find no trace of the principle which he so prettily illustrates at the end of his letter, but which is, on the other hand, the principle of my motor. He shows a motor having sharply-projecting poles and corresponding windings both on the fixed and rotating parts, and he specially mentions in his specification that the number of poles in both parts must be the same, thus producing, as mentioned above, a synchronous non-starting motor. If, as Prof. Thomson says, he could have made these motors work successfully at low periodicities, and was only prevented from introducing them into general use by the high frequencies in vogue in America, I would only point out that there was nothing to prevent the adoption of a lower frequency in the then early stage of development of the alternate-current system, especially when we remember that now, after an immense number of high-frequency plants have been installed, American practice is beginning to come down to lower frequencies. It seems incredible that Prof. Thomson could have been short-sighted enough not to have seen the enormous importance of the practical development of such a motor.—Yours, &c.

Baden. C. E. L. Brown.

TRADE NOTES AND NOTICES.

The 1893 Edition of "The Electrician" Electrical Trades' Directory and Handbook is now ready. This useful book contains over 1,000 pages, and several new and handy features have been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

Tenders Invited.—The Great Western Railway Company invite tenders for Baltic redwood sleepers and crossing timbers and for Quebec yellow pine planks and scantlings. Tenders must be in by Wednesday, April 12th, to Mr. G. K. Mills, secretary, Paddington Station, London.

Tenders Accepted.—The following is the complete list of tenders for lighting the Sunderland Borough Lunatic Asylum, for which the tender of Messrs. Edmundsons (Limited) has been accepted :—

	Without motors.	With motors.
Charlton and Co., Newcastle-on-Tyne	£3,858	£4,108
Edmundsons (Limited), Westminster, London ...	3,673	3,963
A. A. Campbell Swinton, Westminster, London.	4,051	—
Ernest Scott & Mountain, Ld., Newcastle-on-Tyne	3,975	—

——— As announced in *The Electrician* of March 24th, complete tenders have now been accepted for the public street lighting of Londonderry, the gross expenses to date amounting to £15,793, as shown below :—

Accepted tender of Siemens Bros. and Co. for dynamos, arc lamps, conductors, &c.	£8,905
Accepted tender of A. Brown and Sons for engines, boilers, &c.	4,293
Accepted tender of M. M'Clelland for buildings	995
Accepted tender of M. M'Clelland for purchase of site	600
Amount of tender for opening and closing streets	300
Engineer's fees	700
	£15,793

In all 36 tenders were received, some for the whole of the work, others for sections only. The lowest tender was not in all cases

Hosted by Google

accepted, and it will be seen that the work has been entrusted to two firms. Messrs Alex. Brown and Sons did not tender for any of the electrical work, the result being that they have received the contract for all the sections tendered for by them. The highest tender for the whole of the work was £15,979, the lowest £12,903, the accepted tenders amounting to £13,198.

REMOVAL NOTICES.—Messrs. Wake and Sanders, mica merchants, have removed from Fowkes-buildings to 3, Crosby-square, E.C.——The offices of *Lightning* are removed from Charing Cross-road, W.C., to 11, Queen Victoria-street, London, E.C.——The General Hydraulic Power Company (Limited) are about to remove from 46, Holland-street, Blackfriars, to Palace Chambers, 9, Bridge-street, Westminster.

MESSRS. CROMPTON AND CO. (LIMITED).—We have received advance sheets of the new price list of arc lamps, accessories, and sundries issued by this firm, in which some useful information is given, as well as a list of prices and particulars of the arc lamps and accessories manufactured by the firm.

RE WOODHOUSE AND RAWSON UNITED (LIMITED).—Notice is given that a petition for the winding-up of this Company by the High Court was presented on the 16th inst., and that the petition is directed to be heard at the Royal Courts of Justice on April 11th. The petition is at the instance of the Rate and Tax Payers' Assessment Protection Association (Limited), of Serjeant's-inn, E.C., for whom Messrs. Alpe and Ward, of 3, Serjeant's-inn, Fleet-street, act as solicitors. Parties who desire to appear on the hearing of this petition must communicate with the solicitors not later than six o'clock p.m. of April 10th next.

RE A. H. W. RADCLIFFE.—The first meeting of the creditors in this matter will be held at the offices of the Official Receiver, Mr. L. J. Sharp, 23, Colmore-row, Birmingham, on Thursday, April 6th, at 11 o'clock, to receive a report. The debtor's statement shows a total liability of £766. 13s. 6d., with assets estimated to produce £59. 7s., or a deficiency of £707. 6s. 6d. The bankrupt attributes his insolvency to a claim made by the wife of his deceased brother, bad trade, and losses on contracts.

BANKRUPTCY—A second and final dividend of 7s. 5¼d. is payable on and after to-day (Thursday) in the bankruptcy of Frederick George Williams (lately carrying on business as an electrical engineer, at Crown Point, Denton, near Manchester), at the Trustee's, Town Hall, Halifax.

"ENGINEERING AND MINING JOURNAL" (NEW YORK).—The proprietors of this journal have opened a branch office in London at 20, Bucklersbury, E.C., under the charge of Mr. Edward Walker.

"WILLING'S BRITISH AND IRISH PRESS GUIDE."—We can recommend this useful publication, in which are given very exhaustive lists (alphabetical, classified, and topographical) of newspapers, magazines and other publications issued in Great Britain and Ireland, in addition to lists of colonial, American, and foreign newspapers.

MESSRS. RUSSELL AND CO.—This firm have recently been busy wiring and fitting for the electric light a number of different premises, amongst which may be mentioned a residential flat at Albert Gate, the large mansion, 56, Holland Park, a private house at Coburg-place, and a bicycle works at Walham Green. The marine and locomotive boilers and vertical compound steam engine, of which the firm make a specialty, are finding favour with the trade.

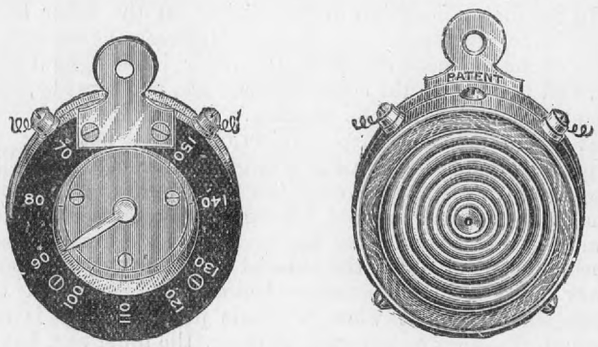
GENERAL ELECTRIC POWER AND TRACTION COMPANY (LIMITED).—The Council of the Royal United Service Institution have instructed this Company to put down an electric lighting plant in the old Chapel Royal, Whitehall, which is being altered for the new museum of the Institution.

MESSRS. GENT AND CO.—This firm have secured the contract for twenty sets of combination telephones and a twenty-station central indicator and switchboard for use at the Holborn Union Infirmary.

INDIA-RUBBER, GUTTA-PERCHA AND TELEGRAPH WORKS COMPANY.—We have received a copy of this Company's last price list of electric light cables and wires, which was noticed in *The Electrician*, Vol. XXIX., p. 653. In the copy now to hand, however, additional divisions have been made in red ink in classes P, Q, T, J, M, which specify vulcanised cables with a nominal resistance of 300 megohms to the mile. Mr. Preece's Paper on insulated conductors has apparently rendered manufacturers alive to the fact that when the thickness of the dielectric is increased in proportion to the weight of copper, the specific resistance by no means remains constant. In fact, the smaller sizes of cable possess a much higher insulation resistance than had previously been ascribed to it, so we have the first ten of the smaller sizes of classes P, Q and T, with an insulation resistance of 1,200 megohms attributed to them instead of 300 as formerly, and 800 megohms are put down for the remaining cables in these classes. In other classes of lead-covered and braided cables similar alterations have been made.

ELECTRICAL POWER STORAGE COMPANY.—This Company send us a copy of a revised price list, in which considerable reductions are made in their specialities, dating from April 3rd. About two years ago, when introducing the new "K" type of cell, the prices per ampere discharge were reduced by about 40 per cent., so that with the further reduction which the Company is now making it is possible to obtain a battery for the same rate of output at less than half the price of three year ago. Another important item, more especially for central stations, is that the battery now occupies only half the space it formerly did. This step must certainly (from the point of view of users in any case) be one in the right direction, and doubtless the increased business resulting from this liberal policy will more than recoup the manufacturers. We are pleased to note that the terms to the trade are to remain the same as previously.

GENERAL ELECTRIC COMPANY (LIMITED).—The third edition of the Electro-Medical Supplies Catalogue issued by this Company is just published, in which illustrations are given of a comprehensive collection of the best apparatus for applying electricity to medical uses. The General Electric Company has, for some years past, interested itself in the collection of this apparatus, and the evidence of their success is shown in thirty large quarto pages filled with illustrations, prices and particulars of a quantity of apparatus in actual use. The illustrations include a variety of coils and batteries, surgical and dental outfits, magnets, electro-medical machines, switchboards for using the current obtained from a central station for galvanisation, electrolysis and faradisation. Electrodes, cauteries, and a large number of other useful instruments complete the catalogue. The whole of the apparatus is of an essentially electrical character. We illustrate a fire-alarm and heat-indicator,



which it is suggested should be of great value in hospitals, sick rooms, &c. It consists of sensitive corrugated diaphragms on the aneroid principle, and gives an alarm by an electric bell when the temperature rises to a degree previously set by an adjustable index finger.

MESSRS. RASHLEIGH, PHIPPS AND CO.—This firm have during the past week secured orders for wiring and lighting the residences of Lady Pearson, Onslow-square, S.W.; Dr. Watson Cheyne, Harley-street, W.; Mrs. Hart, Gloucester-terrace, W.; Mr. Herbert Lousada, Green-street, Park-lane, W.; and additions to the residence of Baron Ferdinand de Rothschild, M.P., at Piccadilly, W.

MILL LIGHTING.—A concession for the establishment of jute factories at Orizaba, Mexico, has been obtained by Mr. T. F. Kinnell, and an extensive jute mill is to be at once erected at Barrio Nuevo, the £100,000 capital for which (the *Mexican Trades* states) has been successfully placed in London. There is an ample waterfall near the site of the mill equal to 11,000 H.P. The huge building is to be lighted throughout by electricity. Pelton wheels are to be exclusively used, and the whole of the machinery is to be driven by electricity.

PULLMAN CAR LIGHTING.—The new Pullman cars erected by the London, Brighton and South Coast Railway Company are lighted throughout by electricity by means of 25 electric lamps in each car. Oil lamps are provided for use when the cars form portion of the trains not electrically lighted. Each seat or chair is provided with an electric bell push connected with the conductor.

LECTURES.—At the Royal Victoria Hall, Waterloo Bridge-road, London, S.E., on the 11th April, Prof. Garnett will lecture on "Some Pioneers of Electricity." Lectures of a popular character will also be delivered on the 4th, 18th, and 25th April.

——— Recently lectures have been delivered on "Electricity and its Applications," by Mr. Mordey, at Stoke-on-Trent; Prof. Jamieson, "On the Hellesen Dry Battery," at Glasgow; Dr. G. J. Stoney at Dublin, and by Mr. Geary at Swadlincote.

BEDFORD.—The Electric Lighting Committee have recommended, and the Town Council have adopted the recommendation, that a sub-Committee of eight be formed, with power to advertise for and

Hosted by Google

receive orders from persons or companies prepared to take over the Provisional Order for lighting the town.

BRIGHTON.—The *Brighton Gazette* recently contained a sympathetic article on the new electric railway scheme, in which reference is made to the "mysterious agency of light and power *from which future generations are expecting so much.*" It would be interesting to learn how the writer ascertained the expectation of future generations.

BRISTOL.—It is anticipated that the electric light will be ready for public supply by September next. Rapid progress is being made with the buildings, and the engines, boilers and dynamos are ready to be placed in position immediately the structure is ready. Messrs. Siemens Brothers and Co. will commence laying the cables forthwith. At the last meeting of the Electric Lighting Committee of the Corporation tenders for the switches, &c., for the Temple Back station were opened and discussed, and were afterwards referred to Mr. W. H. Preece for his report.

DONEGAL, IRELAND.—Messrs. Laurence, Scott and Co. (Limited) are supplying the plant for a lighting installation at the residence of Mr. J. Watt, Claragh, in the extreme North of Ireland, to the specification and under the superintendence of Mr. A. Fahie. The plant includes an oil engine working direct to a Norwich compound dynamo and a set of E.P.S. accumulators controlled by a specially-devised switching arrangement, enabling one-half of the batteries to be charged while the lamp-circuits are running, the engine, while running, working by this means always on a full load.

EAST LONDON.—A public meeting was held last week to support the action taken by the Limehouse District Board of Works in furtherance of the electric lighting scheme for the district. A motion approving of the action of the Board of Works and urging them to bring their efforts to a speedy conclusion was passed unanimously.

EDINBURGH.—The Town Council have drawn up a series of further questions to be submitted to Prof. Kennedy, asking for additional information supplemental to the report which he recently submitted to the Lord Provost's Committee.

FALKIRK.—In reference to the proposed electric lighting of the extensive Fever Hospital at Falkirk, we understand that the result of the inquiries made has led to a proposed extension of the original lighting scheme.

GLASGOW.—Messrs. R. D. Smillie and Co. have just completed a second set of arc-lighting plant for the large steel and iron works of Messrs. David Colville and Sons at Motherwell.

HAMPSTEAD.—The Vestry have referred to their Electric Lighting Committee a letter received from the Local Government Board approving the acquisition of a piece of land of 15,000 square feet area as a site for the new central station.

LANCASTER.—At the last meeting of the Town Council the report of the Electric Lighting Committee was presented, which recommends that a low-tension continuous-current system with insulated cables on the Callendar-Webber system be adopted, and that only a portion of the machinery originally contemplated should be put down. It is intended by the scheme to make provision, so far as cables and buildings are concerned, for the supply of electrical energy for 6,000 16-c.p. lamps, in accordance with the Committee's original scheme. A central station is to be erected in Martin-street yard, on ground belonging to the Corporation, and mains are to be at once laid in several of the principal streets, with an ultimate extension to other districts as soon as the demand justifies the necessary outlay. The Committee recommend the acceptance of the tender of the Brush Electrical Engineering Company for £12,683, which is exclusive of the cost of buildings and the laying of mains, which is to be carried out by the Corporation at an estimated cost of about £5,000. It is proposed to charge 7d. per unit for lighting current.

NEWMARKET.—The Board of Trade have decided to dispense with the formal sanction of the Local Board to the installing of the electric light, but the Local Board was to have an opportunity of showing cause why its consent should not be dispensed with. The Clerk has written to the Board of Trade offering no opposition to the course pursued, but specifying that the public roads should not be open during race weeks.

SHEFFIELD.—An exhibition of electrical lamps suitable for 'bus lighting bicycles, &c., was held in Sheffield during last week in connection with the introduction of electric lighting to the public vehicles of the district.

WEST COWES.—The Clerk to the Local Board at the last meeting read the correspondence between the Electric Light Company and the Board of Trade in reference to the raising of the necessary capital for the purposes of the Company. A letter was read from Messrs. Crompton and Co. (Limited) stating that if the order were placed with them they would commence work at the beginning of April and be in a position to supply the light by July. The question of completing the electric lighting of the town was briefly discussed, and the decision of the Local Board as to its relations with the Company was deferred for one month.

WOOLWICH.—The London County Council have formally disapproved of certain works in connection with the lighting of Woolwich district, details not having been supplied.

TRAIN LIGHTING.—The Great Northern Railway Company of Ireland have for some time past had under consideration the introduction of the electric light for their train service, and on Saturday last a party of gentlemen connected with the Press were afforded an opportunity of testing the completeness of the Company's electrical system, which proved a great success. In a train of five carriages 65 incandescent lamps are fitted. The current is obtained from a set of 25 E.P.S. accumulators in the guard's van which are capable of supplying the whole of the train for three hours without using the dynamo, which is also fixed in the guard's van and is driven off the axle of that compartment. While the train remains at the station the lamps are fed from the accumulators only, but as soon as a speed of from thirty to thirty-five miles is acquired, the dynamo is automatically switched into the supply circuit and is also employed to charge the accumulators. The first-class carriages are each provided with four 5-c p. incandescence lamps, and the second and third-class carriages with two 6-c.p. each, with suitable reflectors, arranged in a manner to supply ample light for reading purposes, and in the first-class are provided with switches to three of the lamps, so that passengers desirous of sleeping are enabled to turn three out of the four lamps off. The dynamo has been specially designed by the General Electric Power and Traction Company (Limited), and the electrical fittings and general work has been done by Messrs. Curtis and Sons, as has also the new system of heating by steam adopted for their general train service by the Great Northern Company.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inven tions, or where complete specification accompanies application an asterisk is suffixed.*

PRINTING TELEGRAPH AND CONSTRUCTION COMPANY OF THE AGENCE HAVAS (LIMITED).—The prospectus of this Company has been issued during the past week, in which some remarkable financial results are set out. France, which until now has practically tabooed the "tape" machine, is all at once to evince an uncontrollable desire to introduce it into every home. It is estimated in the prospectus that 1,000 of the column-printer machines will at once come into use, and that from this source dividends at the rate of about 15 per cent. upon the capital issued by the Company is to be earned. On the directorate is M. D. Monnier, Professor of Industrial Electricity at L'Ecole Centrale de Paris. The secretary *pro tem.* is Mr. T. J. Ford, and the temporary offices are situate at 10 and 11, Queen Victoria-street, London, E.C. The total capital is £110,000 in shares of £5 each, of which the vendors (Messrs. R. D. Radcliffe and Viben-Smith) take 3,100 fully-paid shares (£15,500) and £59,500 in cash or shares at the option of the Directors, leaving £40,000 as working capital, supposing the whole to be subscribed without underwriting commission. Subscriptions are payable—5s. on application, 15s. on allotment, £1 on the 5th prox., £1 on May 5th, and £2 on June 5th next. The list closed on Wednesday.

COMPANIES' MEETINGS & REPORTS.

Direct Spanish Telegraph Company (Limited).

The thirty-ninth ordinary general meeting of the Company was held at Winchester House, Old Broad-street, on March 24, 1893, under the presidency of Mr. Edmund Etlinger.

The MANAGER (Mr. Ch. Gerhardi) having read the notice calling the meeting,

The CHAIRMAN said: Before commencing our business to-day, I regret to have to state that our Chairman (Sir James Anderson) is absent owing to illness; but I am, on the other hand, glad to hear this morning that there is a decided improvement in his condition. I, therefore, hope that before long we shall have the pleasure of again seeing him among us (cheers). In accordance with our usual practice, I will now ask the Manager to read the minutes of the last general meeting.

The MANAGER having read these minutes,

The CHAIRMAN said: The half-year under review to-day—namely, the half-year ended December 31, 1892—has been very uneventful. Our traffic receipts have shown a very slight increase, but a very slight increase only. On the other hand, our expenses have been very much the same as they were before. Now, considering that the commerce of the world has not been brisk—in fact, I believe people say that it has been very slack—and also considering that there has been no political event which would throw any extra work on Spanish international wires, I think we may be satisfied with the result we have obtained; the result being that we are better off by £410 this half-year than we were a year ago for the corresponding period of 1891. We may also congratulate ourselves upon the fact that during the half-year there has been no occasion to spend any money on cable repairs, and the small works we had to carry on in connection with the land-lines at Falmouth, Bilbao, and Barcelona have been completed for the small expenditure of £171, which has been charged against revenue. If you will turn to the balance-sheet, at pages 8 and 9, you will see that we expended nothing on capital account; we have raised no additional capital, and we have contracted no loan. The debentures remain exactly as they were before, but as you were told at our last meeting, these debentures fall due in May, 1894. That fact, however, I think, need cause us no anxiety whatever. We shall by that time have a reserve fund of £40,000; we have a yearly net income of £14,000, and we have uncalled capital of £13,000. Under those conditions there can be no difficulty whatever, when the time comes, of arranging about these debentures. To-day there is no occasion to go into the matter at all. As to the reserve fund, it stood, at the end of 1892, at £30,331, whereas this time last year it stood at £23,946. We have therefore increased our reserve fund during the past year by £6,386, and I think you will regard that as satisfactory. With reference to the outstanding liabilities of £12,688, they represent the balances of telegraph accounts with other telegraph administrations due by us at December 31, 1892, but these amounts are more than counterbalanced by those due to us by foreign administrations, which come to £13,000. I need hardly say that since the 31st of December last, both these sums have been very much reduced. The balance to profit and loss account amounts for the half-year to £5,438. 19s. 7d., which represents our profit for the half-year, less the debenture charges for that period, and it is really the amount which we have to deal with on this occasion. If you refer to the revenue account at pages 4 and 5, you will find that our expenditure for the second half of last year was £4,982. 4s. 2d., whereas the expenditure for the corresponding period of 1891 was £5,381. 0s. 7d., so that in the past half-year our expenditure was less by £398. 16s. 5d. If you add to that, that our total receipts have increased by the very small amount of £11. 10s. 3d., you will find that the total result of the half-year's working is that we have increased our receipts by £410. 6s. 8d. That is not much, but it is not unsatisfactory under the circumstances. The balance of profit for the half-year is £7,252. 9s. 7d., while last year it was only £6,842. 2s. 11d. That, of course, is the exact difference I gave you before of £410. 6s. 8d. to the advantage of this half year. At the bottom of the same pages you have the appropriation account, a statement showing how the £5,438. 19s. 7d. is dealt with. In the first place we put, as per arrangement, £2,500 to the reserve fund; secondly, we also carry to the reserve fund £442 on account of the repayment of a certain amount which we borrowed from the reserve fund in 1891, for cable repair purposes. The total amount then repaid of the sum so borrowed will be £883, leaving £1,393 to be repaid out of future half-years. Then we recommend you to declare the preference dividend at the rate of 10 per cent. per annum, amounting to £1,462. 10s., and a dividend of 4 per cent. per annum on the ordinary shares, amounting to £1,034. 9s. 7d., together making £2,496. 19s. 7d. These sums will absorb the whole of the available balance of £5,438. 19s. 7d. I will now for a moment ask you to turn to the report, and I will refer you particularly to paragraphs 2 and 3. If you read those paragraphs by themselves as they stand there, they would not show you the same result as I have indicated; they would not show as great an increase of profit as £410. The explanation of that is that in the report, when we deal with the receipts, we only deal with traffic receipts. We do not in those paragraphs allude to other receipts, such as transfer fees and interest on money from our bankers; and in regard to working expenses, we only include the regular working expenses for doing message business, not special expenses, such as the construction and repair of land-lines and so on, to which I just now referred. You must not therefore read those two paragraphs by themselves but in connection with the accounts as I have done, when you find that the increased profit for the half-year has been £410. Then, the fourth paragraph tells you that the Company's cables and the land-lines in connection with them have continued in good working order throughout the half-year. I have already

Hosted by Google

told you that on cables we spent nothing last half-year. I now come to paragraph 5, which is as follows:—

"The Directors, with a view to strengthen the good relations existing between the Company and their Staff, propose to follow the practice adopted by many companies, in assisting the employés to make provision for their old age, or for their representatives after death. Arrangements have been made for taking out Endowment policies on which, under certain conditions, the Company pay one-half of the premiums. It is calculated that the amount which the Company can be called upon to contribute will not exceed £250 per annum."

I have very little to add to that paragraph, because it speaks for itself but I may say that the Directors feel confident that every shareholder will heartily concur in this arrangement, by which, at a moderate sacrifice, the Company will assist the employés in making provision for their old age, or for their families after death. On the one hand, the arrangement will relieve the employés to some extent in their natural desire to provide for their families in the future, and on the other hand, it will indicate that the scale of salaries, as now arranged, will be permanent. I commenced by saying that the half-year had been uneventful, and therefore I am not able to make you a long speech. I will therefore conclude by moving—

"*That the report and accounts now presented be and are hereby received and adopted.*"

Mr. J. DENISON PENDER: I will second that.

The CHAIRMAN: Before submitting that to the meeting I will ask if any gentleman has any question to put. No shareholder rising to address the meeting, he submitted the resolution in the usual way, and declared it carried unanimously. Continuing, he said: The next resolution is—

"*That the dividend at the rate of 10 per cent. per annum (less income tax) on the preference shares and a dividend at the rate of 4 per cent. per annum (free of income tax) on the ordinary shares, both for the half-year ended December 31, 1892, be and are hereby declared.*"

Mr. J. DENISON PENDER: I have much pleasure in seconding that.

The resolution was carried unanimously.

The CHAIRMAN: The next resolution refers to the re-election of Directors. You are aware that, by our Articles of Association, two Directors have to retire every year, and it so happens that on this occasion Mr. Pender and I retire. We are both willing to be re-elected if it pleases the shareholders to do so, but we find some difficulty in proposing our own re-election.

Mr. JOHN GLOVER: I beg to move—

"*That Mr. Edmund Etlinger and Mr. J. Denison Pender be and are hereby re-elected Directors of the Company.*"

Mr. J. T. CROWE: I will second the resolution with much pleasure.

The motion was carried unanimously.

The CHAIRMAN: There is only one more resolution, which refers to the auditor.

Mr. WM. HIBBERDINE: I beg to propose—

"*That Mr. Herbert R. Duke be and is hereby re-elected Auditor for the present year, with a remuneration of 20 guineas.*"

Mr. CROWE seconded the motion, which was carried unanimously.

The CHAIRMAN; That is all the business we have to transact to-day, and I am much obliged to you for your attendance.

Mr. GLOVER: Before we separate it is always usual to propose a vote of thanks to the Chairman and Directors. I am very sorry to see that our Chairman is not here to-day. I do not not say that out of any disrespect to our present Chairman, but we should all have liked to see our old friend Sir James Anderson with us. I beg to propose a vote of thanks to the Chairman and the Directors.

Mr. CROWE seconded the motion, which was unanimously carried.

The CHAIRMAN: I am sure that Sir James Anderson will be very glad to hear the remarks you have made, and on his behalf and on behalf of the Directors I beg to thank you.

The proceedings then terminated.

Notting Hill Electric Lighting Company (Limited).

The annual general meeting of this Company was held on Monday last at the Company's central station, Bulmer-place, Notting Hill-gate, Prof. Wm. Crookes, F.R.S., presiding.

The SECRETARY (Mr. W. H. Fox) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Ladies and gentlemen, you will doubtless think it unnecessary for me to refer to any great extent to the accounts, as they are published in such full detail that I think they really speak for themselves. There are one or two points, however, which perhaps you might feel interested in having a little information on, and I will therefore devote a few minutes to these matters before moving the adoption of the report and accounts, although I think most of the subjects are explained in the Directors' report, which you have before you. In table No. IV. there are one or two items on the debtor side to which I must draw attention. The first is the cost of hiring temporary boilers, £16. 17s. 6d., and to this may be added a further sum of £18. 12s. 6d. for wages and stores in connection with the same, making a total of £35. 10s., which will not appear in the accounts for this year as the boilers have been dispensed with, our load now being sufficiently good to render the continued use of our large boilers economical. Another item to which I would refer is rents payable, £161. 10s., which, as stated at the foot of the revenue account, includes a sum of £100 for rent of special local office at 105, High-street, Notting Hill, which has now been given up, as it was not considered advisable in the interests of the Company to take a further lease of the premises, and, as a matter of fact, the Directors had previously endeavoured to let the house, but could not do so at a reasonable rent. There will, therefore, be a saving of £135. 10s. in the accounts for this year from these two sources, and we also do not expect that the law expenses will be anything like so large as those appearing in the accounts before you. As you will see by the credit side of account No. IV. the amount of revenue from the sale of current for the year was £2,518. 17s. 1d., which shows a very satisfactory increase over the £999. 10s. 6d. earned during the previous seven months. The bad debts for the year amount to only £5. 10s. 2d., which, I think, reflects credit on the management in the choice of customers, and in requiring guarantees in doubtful cases. Perhaps a little explanation is needed with regard to the fee of £250 from the New Telephone Company (Limited), which appears in the revenue account. The fee was paid by them to this Company merely for entering into an agreement whereby amongst other things the Company agrees to allow the Telephone Company to lay wires in our culverts for telephonic purposes at a certain rental per mile of wire, the minimum rental being fixed at £100 per annum, but the provisions of the agreement take effect conditionally upon the granting of the necessary approval by the Board of Trade and other Authorities, which I understand has not yet been obtained. We now come to Table V., the net revenue account, on the debit side of which appears an item of £92. 16s. 10d. for "interest on loans," and we do not anticipate any similar liability being incurred this year, as the charge is for interest payable to the contractors in connection with the construction of the Phillimore district mains, to which I shall again refer. The debit balance of £617. 5s. 7d., which appeared on the net revenue account at the end of the previous year has been reduced to £347. 16s. 4d., but this is chiefly through the amount of £250 of Directors' fees being re-credited in the accounts, and perhaps a little further explanation would not be out of place here with regard to Directors' fees. As you are aware, the total amount of fees payable to the Directors under the Company's Articles of Association is £1,000 a year, and as was stated in the last report, the Directors had not drawn their fees for the quarter ending December 31, 1891, and have not drawn any since that time; therefore, at the 31st December last, the total amount of fees due to the Directors was £1,250. In view, however, of the present struggling position of the Company, the Directors have agreed to return to the Company half of the fees due, and have also agreed to accept only half fees for the present year, and they have also gone further and agreed to postpone their claim to the half fees due, together with those for this year, until the accounts have been presented to the shareholders in 1894. An agreement embodying this arrangement has been prepared and signed by all the Directors, and I am sure you will all agree with me that the Directors have acted in a most generous manner with regard to this. As regards the depreciation fund account (No. VII.), you will notice the Directors have not thought it necessary to provide for depreciation, as they are advised that the charges in the revenue account under the head of repairs and maintenance are sufficient for the purpose; and I would add that the mains and machinery are kept in such a thorough state of efficiency that it certainly does not appear to the Board to necessitate, at any rate at present, any special provision for this being made. I do not think there is anything in the general balance-sheet requiring comment. The last account is the statement of electricity generated, sold, &c., and I think the only figures requiring any special explanation in this statement are those appearing under the head of "Quantity not accounted for." Of the 13,061 units said to be absorbed by the batteries, I think it might be fairer to charge the batteries with only 9,000 units, the balance being debited to losses in meters, and the difference between the current at 101 volts we actually give consumers and the current at 100 volts that we charge to them. The 2,268 units lost in the mains represent the amount of energy expended in overcoming the resistance of the mains. The actual quantity not accounted for is, therefore, only 61 units, and I do not think any other company in London can show such a satisfactory result. During the year we have made several extensions of the mains, but by far the principal one was the extension to the Phillimore district, and it was with the special object in view of making this extension that the ordinary preference shares were issued; but before finally deciding to extend to this part of the area, the Directors took great care to ascertain the amount of support likely to be received in the neighbourhood, and on finding that there was every likelihood of obtaining a satisfactory return on the capital outlay, it was decided to carry out the work, and the Directors are pleased to find that their estimate was correct, as we have already a good number of houses connected on the mains of this extension. It was at one time thought that it would be necessary to have a battery station to supply this district, but I am glad to tell you that it was found possible to supply the current required without the aid of this, and we therefore saved a large capital outlay in that direction. Since the end of last year the Company has made a further extension to Observatory-gardens and Observatory-avenue, but in this instance, and in the case of several other small extensions carried out last year, the Directors have obtained advances from those interested at least equal to the bare cost of the work done, to be repaid by not charging the consumers on the extensions for any current consumed until the loan has been paid off, and we find that this plan acts very well. The item of £485. 5s. 7d. in No. VIII. account, debtor side, shows the deposits made in such cases to cover the guarantees. These are only repayable by our not charging the consumers for current till the loan is paid off, so you see the Company does not run any risk with these minor extensions. The guarantees vary in terms according to the necessities of the case, and several have already run off. I think I may say that these few cases are the only ones in which there are any charges on the Company. The cost

Hosted by Google

of the Phillimore extension has been about £6,500. The number of houses on the extension already wired and lighted is 17, and the number of lamps reduced to a uniform 16-candle unit is 1,351. The estimated revenue from this extension is £500 in the current year, and £600 in the year 1894. As you are aware, the Directors obtained the sanction of the shareholders in May last to issue the balance of the ordinary shares, amounting to £29,980. in the form of ordinary preference shares, bearing a cumulative dividend of 6 per cent. These shares were in the first place offered to the shareholders of the Company in proportion to their holdings, and up to the 31st December last 796 shares were taken up, representing £7,960, and since that date the Directors have allotted 20 in addition. I think practically the whole of the capital received from the issue of these shares has been spent in making extensions of the mains and in the purchase of additional machinery required owing to the increased area supplied. No money is now owing to Messrs. Crompton and Co., the contractors, for construction though an arrangement was made that the money could have been borrowed in the event of the preference issue not having been successful. Our property, with the trifling exception of the extensions made with private money, as already mentioned, is quite free, being saddled with no mortgages, no debentures, and no charges. When I had the pleasure of addressing you at the general meeting last year we had 77 houses connected to the mains representing 6,056 8 c.p. lamps, which by the end of December last had been increased to 124 houses representing 9,438 8 c.p. lamps, or an increase of 47 houses and 3,382 lights, and I am very pleased to be able to say that so far as the present year has gone the increase in the number of houses in proportion to the whole of last year has been slightly larger, so that if the steady increase is maintained (as we have reason to expect will be the case) we may expect to be very shortly in an extremely sound position and yielding to the shareholders a substantial return on their investments. The present number of lamps on our mains is 9,854, bringing in an estimated revenue of about £3,500 per annum, but by the end of 1893 we may reasonably expect the increase of lamps to be such as to raise the yearly revenue to about £4,000. I am very pleased to say that during the year the mains and machinery have done their work in a most efficient and satisfactory manner, and with the exception of three instances during the winter, when some of the mains were flooded owing to the bursting of the water mains, no accident of any kind has occurred. In each case the flooding of the culverts happened in frosty weather, and the escaping water undermined that particular part of the roadway and filled the culvert with water, consequently making a connection between the strip and causing a loss of 240 units. In the places, however, where these accidents happened the Directors have thought it advisable to specially drain the culverts, and they are also making representations to the London County Council with a view of preventing a re-occurrence of the nuisance, as it appears the real cause of the trouble is the blowing out of the fire plugs, which are old-fashioned wooden ones, and ought to be replaced by something of more modern type. There was, I think, only one other thing which occurred during the year to trouble us, and that was a considerable leakage of water into the basement of the central station which was likely to damage the foundations, and it took us a considerable time to ascertain the source from which this came, but I am glad to say that it was at last discovered, and by constructing some drains just outside the station the leakage has been stopped. There is one thing which has, I regret to say, not quite reached our expectations, that is the yield per lamp per annum. The estimate I gave last year was 10s. per lamp, and from the results obtained by other London companies there was every reason to believe that we should exceed this sum. We find, on going into details, that the actual revenue per lamp per annum is only 7s. It is difficult to account for this difference. Possibly it is owing to Notting Hill being of a higher elevation than that of the surrounding areas, and consequently benefiting more by daylight, and also being less affected by foggy weather. It is also noticed that, as confidence in the stability of the light grows, customers wire their houses and fit up more lamps than they intend to use ordinarily. At first the tendency is only to put lamps where they are wanted almost nightly. Afterwards, when the bugbear of increased expense is found to be a negligeable item, consumers go to the opposite extreme and when they are wiring their houses put up lamps where they are merely decorative, or are only likely to be used on special occasions of balls and receptions. It is with the object of increasing the amount of revenue per lamp that we have instituted a scale of rebates, which, however, consumers do not participate in until their revenue per lamp for the year has reached the standard price of 10s., when a rebate of 5 per cent. is allowed, the highest reduction being 25 per cent., in cases where the average yield per lamp reaches the large amount of 30s.; and when we consider that the average yield per lamp on the whole of the system only reaches 7s. per annum, you can well understand that cases in which the full rebate can be claimed are few and far between. There are 19 consumers who will, according to last year's statistics, benefit by the rebates. One would get a reduction of 25 per cent, one 20 per cent., three 15 per cent., four 10 per cent., and ten would get a rebate of 5 per cent. The total amount of these reductions would be about £75. The Board are now considering a scheme for cutting down the expenditure to the lowest point of safety. I have already dealt with the question of their own remuneration. The other savings that they see their way to, would amount to somewhere about £500 a year, and include giving up the City office, the shop, the stables, &c. As all these reductions will not commence at once, not more than £400 will be saved this year. I have much pleasure in announcing another saving which we shall also get the benefit of next year. Our auditors have, as already stated in the report, reduced their fee from £31. 10s. to £15. 15s. We are now contemplating extending our work westward, and so filling up the remainder of our district. But before going on we are waiting to hear what support we can secure. The contemplated expense will be, with a battery station for the Melbury Road district only, about £16.000. But with the complete installation of boilers, engines, dynamos, batteries, &c., the cost will be about £36,000, as stated in our report for 1891. It will be useless to spend thousands for a revenue which will not even pay the expenses of maintenance of cables, let alone the supply of current. The basis that the Directors go on is that the *gross* revenue should be on such a scale as to repay the actual extra capital expenditure required in from 4 to 5 years. This would mean that (without any increase) they might get 5 per cent. for their *extra* capital at the end of 5 years. If we asked for less than this the business of the Company would be too speculative. Such procedure was unavoidable at the outset when there were no data to go on, but now it would be very wrong not to secure our way as we go along. In conclusion, I would draw the shareholders' attention to the fact that in view of the steady and continued increase in the Company's business, the future prospects of the Company appear very bright, and I hope that on the next occasion when I have the pleasure of addressing you, I shall have to propose a resolution which I regret this year it is impossible to do, namely, the declaration of a dividend, and I now beg to propose :—

"*That the report of the Directors and the accounts to December 31, 1892, submitted to this meeting be, and the same are hereby, approved and adopted.*"

Mr. SIDNEY WATERS, in seconding the motion, said that it was quite evident that the rate of progress in a company of this kind to a very large extent depended on the general commercial prosperity of the country. The Company was just started after the great Baring failure, and since then there had been a period of general depression which had weighed very heavily on the commercial world and the prosperity of England. That period was they hoped now passing away, and with the revival of trade and better times a company of this kind would be the first to benefit. During times of depression people felt reluctant to go to the expense of wiring their houses and incurring any extra expenditure. Now, however, that there were hopes that the depression was disappearing, they hoped that the number of houses that would come on their system would be materially increased.

The resolution was carried *nem. con.*

Mr. J. T. JERVIS proposed and Mr. DUTTON seconded the re-election of the retiring Directors, Prof. Crookes and Mr. S. Waters.

The motion was carried unanimously.

The CHAIRMAN having briefly expressed his acknowledgments on behalf of Mr. Waters and himself,

Mr. BENSON moved the reappointment of the auditors, Messrs. Deloitte, Dever, Griffiths and Co., at a renumeration of 15 guineas.

Mr. ASTON WEBB seconded the motion which was also carried *nem. con.*

Mr. BENSON, in proposing a vote of thanks to the Chairman and Directors for their services during the year, said that these gentlemen had behaved very liberally to the shareholders in remitting a large portion of their fees, without any urgent request from the latter. They had not only done so, but they had postponed the payment of what was legally due to them, for which the shareholders were very much indebted to them. He trusted that the hopes of the Board would be realised, and that they might soon see a dividend on their capital.

Mr. MATTERSON seconded the motion, which was cordially carried.

The CHAIRMAN, in returning thanks for himself and his colleagues, remarked that he did not believe that there was a harder working Board in London, and that it was by reason of their exertions that the Company had been brought into, he would not say such a flourishing condition, but into one so full of promise for the future.

The proceedings then terminated.

Anglo-Portuguese Telephone Company (Limited).

The following report of the Directors of this Company was presented at the sixth ordinary general meeting, held at the offices of the Company on Tuesday last :—

The amount to the credit of profit and loss account, after making all deductions, and including the balance brought from last year, is £6,099. 16s. 3d. The Directors recommend that of this amount £2,500 be applied to the payment of a dividend at the rate of 5 per cent. per annum ; that £2,000 be placed to reserve fund, and that the balance, £1,599. 16s. 3d., be carried forward to the current year's accounts. Acting upon the instructions of the auditors, the assets and liabilities in Portugal have been made up at the exchange ruling on December 31st last.

The expenditure on capital account for the year amounted to £3,256. 4s. 9d.

The number of paying subscribers at December 31st last was—

In Lisbon, 1,066, of a gross annual value of	£7,870	
„ Oporto, 1,125, „ „ „	6,140	
		£14,010

showing a total increase in subscribers of 40 and in value of £274, over the preceding year.

The shareholders will be pleased to learn that a decree was issued in December last by the Portuguese Government dealing with unauthorised lines, and regulating the powers of municipalities where the working of the telephone is concerned, which your Directors hope will have a beneficial effect upon the Company's operations.

The Directors have to record with feelings of deep regret the death, in September last, of their esteemed colleague, Mr. Richard Van Zeller.

At the meeting the dividend referred to in the report was approved, and the report was adopted. Sir Alex. Armstrong and Senhor E. Pinto-Basto were re-elected as Directors, and the auditors, Messrs. Deloitte, Dever, Griffiths and Co., were re-appointed.

The Consolidated Telephone Construction and Maintenance Company (Limited).

An extraordinary general meeting of the members of the Consolidated Telephone Construction and Maintenance Company (Limited) was held at Winchester house, Old Broad-street, London, on Tuesday, Mr. C. L. W. Fitzgerald presiding.

The SECRETARY (Mr. Chas. Curtoys) having read the notice convening the meeting,

The CHAIRMAN said that they had met simply to confirm the resolution passed at the last meeting. It was a mere matter of form. He would simply say in a few words how that resolution came about. It was because they had received a considerable sum of money from the sale of the Austrian securities which the Consolidated Company held. He need not detain them, and he would merely move the confirmation of the following resolution :—

"*That the capital of the Company be reduced from £207,545, divided into 75,000 Preference shares of £1 each, 75,150 Ordinary shares of £1 each, and 224,850 Ordinary shares of 1/s. each, to £234,938, divided into 47,363 Preference shares of £1 each, and 75,150 Ordinary shares of £1 each, and 224,850 Ordinary shares of 10s. each ; and that such reduction be effected by returning the amount of £1 per share credited as paid upon each of the 27,637 issued Preference shares of the Company to the holders thereof, and thereupon cancelling such shares, and by returning 2s. per share to each of the holders of the 224,850 issued Ordinary shares of the Company, and by writing off each of the said 224,850 Ordinary shares the sum of 2s. per share as being capital unrepresented by available assets.*"

Sir ALEXANDER ARMSTRONG, K.C.B., seconded the resolution.

The CHAIRMAN, in reply to Mr. E. O. Walker, said that the Directors had taken the best legal advice in Vienna on their position. He himself and two of the other Directors went out there, and after ascertaining how matters stood, they decided to take what money they could get rather than risk the uncertainties of the law. They lost nothing in money. They took shares from the Austrian Company for the concessions, therefore they did not lose the money, but did not make so much as they hoped to do. The preference shareholders were paid off because they had a priority of claim.

The resolution was carried, and the proceedings ended.

Chatham, Rochester and District Electric Lighting Company (Limited).

An ordinary meeting of the shareholders of this Company was held at the Sun Hotel, Chatham, on the 21st inst., Mr. H. Jasper in the chair.

The CHAIRMAN, in moving the adoption of the report and balance sheet, said doubtless they would all be surprised, and it was very possible that they would be disappointed, especially having regard to the fact that although the Company had been at work so many years without attempting to declare a dividend, that there was none that year. He must say that he felt very justified on the information he received from the secretary, not only to hope, but to feel assured they would have been in the position to declare a dividend of 2½ per cent. at least. He was sorry that was not the position that day—they were not able to get the figures out at that time accurately. He was basing his figures upon the actual working expenses of the time as they thought they were. Coal, however, and other expenses had been heavier than they thought, and they would see they had only been able to make a profit of £62. When he told them that that profit was made in the last quarter of the year, they would readily understand that it was very difficult to be able to say what amount of profit would be made in this year. They were deceived in regard to the consumption of coal and other expenses, but he was happy to say that their position that day was due entirely to the fact that they had in their Managing Director a gentleman that thoroughly understood the science in which their money was invested. Seeing there was only a profit of £65. 5s. 5d., it was useless to think of dividing that small sum. Their estimate for the year was at the rate of 4½d. per trade unit. An important question arose here—they would ask why was it they were not making a profit; but if they made a profit at 4½d. per unit, it meant that their customers would have to pay more. They found that although their output of electricity was considerable they were getting a small percentage per uuit because of the enormous waste. They had a large number of customers who were consuming more than the Company contracted to supply them. They had also had the assurance of a customer who had put in one of the new meters, that he found that the amount he had to pay by the meter was smaller than he anticipated, and according to what he consumed now he would be paying less with the meter than when under contract, thus the contract was not the most favourable terms for the Company. A considerable number of those meters, the very best and the only meter that was passed by the Board of Trade, would be put in as quickly as possible, to the mutual advantage of the Company and the consumer. They could look forward with confidence to be in a position to declare an interim dividend in June next. He did not suppose it would be more than 2½ per cent. In regard to depreciation, they would have to consider that in the meantime.

A lengthy discussion took place as to the Chairman's having undertaken the responsibility of carrying out the contract for the underground mains, it being contended by some shareholders that his terms were hard upon the Company, as they said he had taken shares to the amount of £8,315 in return for advancing £4,150. It was, however, shown that the secretary had been unsuccessful in his appeals to several capitalists to advance the Company the necessary money at 6 per cent., and as his co-Directors were equally unwilling to assume or share the responsibility for the contract, the Chairman had undertaken it himself in order to save the Company from losing their Provisional Order, which would be the case if underground mains were not substituted for the overhead cables very shortly.

The report was ultimately adopted, and the meeting separated with a vote of thanks to the Chairman and Directors.

The report and balance-sheet contained the following :—

"Your Directors have much pleasure in presenting their fifth annual balance-sheet made up to December 31, 1892, and in calling attention to the fact of their having made a profit upon the actual generation of the electric light of £62. 5s. 5½d. Your Directors were very much in hopes of being able to delare a dividend on the past half-year, but as the profit has only been made upon the last quarter it is not sufficient. They are, however, of opinion that they will be able to declare an interim dividend in June next. This is practically owing to their having secured the services of an eminently qualified electrical engineer in the person of Mr. Mark Henry Hurrell, M.I.E.E., who has been appointed Managing Director, as the profit that has been made has been effected during the latter part of the year since Mr. Hurrell's appointment. Several new customers have been connected up during the past year, and many more are waiting to be supplied as soon as the underground system of mains has been completed. In consequence of the severe frost and heavy rains the main circuits have been delayed, but they are now rapidly approaching completion. A great part of the new machinery is in course of erection at the central station, and the sub-stations are ready to receive the transformers which are now lying at the works ready to be placed in position. Your Directors desire to inform the shareholders that a communication has been received from the Mayor and Corporation of Chatham, inquiring if the Company are disposed to sell the undertaking to the Corporation, and on what terms. In the interest of the shareholders your Directors considered it was inadvisable to enter into negotiations at present, and have informed the Corporation that when the works in progress are completed they will be willing to receive a deputation to inspect same and to confer further upon the subject."

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

THOMAS HOLCROFT AND SONS (LIMITED).—Capital £120,000 in 11,900 shares of £10 each and 1,000 shares of £1 each, electrical, mechanical and general engineers, suppliers of electricity and of light, heat and motive-power generally, &c.

E. C. AND J. KEAY (LIMITED).—Capital £50,000, in £10 shares. Electrical, mechanical and general engineers, at the Cyclops Iron Works, West Bromwich, Staffs. ; the James Bridge Works, Darlaston, Staffs. ; and Princes-chambers, Corporation-street, Manchester.

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED).—The annual return of this Company, made up to March 8, 1893, has been filed. The whole nominal capital of £300,000, divided into 100 founders' and 59,900 ordinary shares of £5 each, has been taken up, the full amount called, and all calls (£300,000) paid.

CITY NOTES, &c.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend for the quarter ending March 31st of 12s. 6d. per cent. on the ordinary stock, and 25s. per cent. on the preferred stock (less income tax), payable on May 1st to the stockholders registered on the books of the Company on March 31st.

BELL TELEPHONE COMPANY (OF AMERICA).—This Company has increased its capital by a further two and a-half million dollars.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended March 26th were £859, as against £818 for the corresponding period of last year, being an increase of £41. The total receipts for half-year amount to £11,270 against £10,222 in the corresponding period of 1892, being an increase of £1,048.

COMPAGNIE FRANCAISE DES TELEGRAPHES SOUS-MARINS.—It is reported that this Company is about to issue 1,500,000fr. of debentures, in order to secure the annual subvention of 200,000fr. to be paid by the French Government on the laying of a cable between New Caledonia and Australia.

COMPANIA GENERAL MADRILENA DI ELECTRICIDAD.—This Company made a net profit last year of £15,600, and a dividend of 6½ per cent. has been declared.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The Directors of this Company have resolved upon the payment of an interim dividend of 3s. 6d. per share, free of income tax, being at the rate of 3½ per cent. per annum, for the quarter ended March 31st ; the dividend to be payable on and after April 24th.

GLOBE TELEGRAPH AND TRUST COMPANY (LIMITED).—An interim dividend of 2s. 3d. per share has been declared by the Board, payable on the 18th proximo.

Hosted by Google

HOBART TRAMWAY COMPANY (LIMITED).—An extraordinary general meeting of this Company is to be held at College Hill-chambers, E.C., on April 6th for the purpose of considering a proposal to change the name of the Company to the Hobart Electric Tramway Company (Limited).

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended March 24, 1893, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,348.

BOROUGH OF BRIGHTON.

ELECTRICITY WORKS.

NOTICE is Hereby Given, that the COUNCIL of the said Borough will receive TENDERS from such persons as may be willing to enter into a Contract for the SUPPLY and ERECTION of the following PLANT in connection with their Electricity Works.

1. Lancashire Boilers.
2. Steam and Water System and Piping, with Feed Pump.
3. Steam Dynamos and a Motor-Dynamo.

Separate Specifications can be obtained on application at my office at the Town Hall, Brighton.

Sealed Tenders, addressed to me and endorsed "Tender for Lancashire Boilers," (or as the case may be), must be left at my Office before Ten o'clock in the forenoon on MONDAY, April, 17, 1893.

A fee of One Guinea will be charged for each Specification, which sum will be refunded on the return of the Specification accompanied by a bona fide Tender on or before the above-mentioned date.

The Council do not bind themselves to accept the lowest or any Tender.

FRANCIS J. TILLSTONE, Town Clerk.

Town Hall, Brighton, March 29, 1893.

COUNTY BOROUGH OF SALFORD.

ELECTRICITY SUPPLY.

The GAS COMMITTEE are prepared to receive TENDERS for the SUPPLY and ERECTION of MACHINERY for the above Works.

Copies of the Specifications, which are in the following Sections, viz.—

Contract No. 2. Steam Boilers, &c.
Contract No. 3. Steam Engines, Pipes, Travelling Crane, &c.
Contract No. 4. Electrical Plant.
Contract No. 5. Electrical Mains, &c.

may be obtained (on payment of the sum of £5 for each Section, which will be returned on receipt of a bona fide Tender) from the Gas Engineer, Gas Offices, Salford.

Full information may be obtained on application to the Electrical Engineers, Messrs. Kincaid, Waller and Manville, 29, Great George-street, Westminster.

Sealed Tenders, endorsed "Tender for Contract No. ," addressed to the Chairman of the Gas Committee, to be delivered to me before 5 p.m., on THURSDAY, the 4th May next.

By order,

SAML. BROWN, Town Clerk.

Town Hall, Salford, 5th April, 1893.

CITY OF MANCHESTER.

The PUBLIC FREE LIBRARIES COMMITTEE are prepared to receive TENDERS for the Installation of ELECTRIC LIGHT WIRING and APPLIANCES for the Free Reference Library, King-street. Specifications may be seen at the Library.

Tenders, to be marked "Tender, Electric Lighting," and addressed to the Chairman of the Public Free Libraries Committee, Free Reference Library, King-street, Manchester, must be delivered not later than APRIL 15th.

"THE ELECTRICIAN" PRINTING AND PUBLISHING CO., Ltd., Salisbury-court, Fleet-street, London, E.C.

JOURNAL OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

Edited by F. H. WEBB, Secretary.

Part 104.—Containing the Conclusion of the Discussion on Professor J. A. Fleming's Paper "EXPERIMENTAL RESEARCHES ON ALTERNATE CURRENT TRANSFORMERS," and his reply. "TESTING AND WORKING ALTERNATORS," by W. M. Mordey, Member, and Discussion thereon, also two interesting Original Communications, viz., "NOTES ON A SELENIUM CELL," by E. O. Walker, C.I.E., Member, and "A NEW DANGER TO WHICH UNDERGROUND WIRES IN INDIA ARE EXPOSED," by C. V. Luke, C.I.E., Member. Classified List of Articles relating to Electricity and Magnetism contained in some of the Principal Technical Journals during the months of January and February, 1893, and Abstracts of some of those published during the months from June to December, 1892.—PRICE TWO SHILLINGS AND SIXPENCE.

London: E. and F. N. SPON, 125, Strand, W.C.

NOW READY.

"HOUSE LIGHTING BY ELECTRICITY,"

POPULARLY EXPLAINED.

By ANGELO FAHIE, M.I.E.E.

Large 8vo. Illustrated. Paper Cover, 1s. Cloth and gilt, 2s.

LONDON: E. and F. N. SPON. DUBLIN: J. FALCONER. NEW YORK: SPON and CHAMBERLAIN.

To be had of all Booksellers.

"THE PATENTEES' HANDBOOK,"

BY

J. G. LORRAIN, M.Inst.E.E., M.Inst.M.E.,

CHARTERED PATENT AGENT,

Gives full information and advice to intending Patentees. Sent post free on application to Mr. J. G. LORRAIN, Norfolk House, Norfolk-street, Strand, London, W.C.

Messrs. WILLIAMS and NORGATE, Importers of Foreign Books, have weekly parcels from the Continent with all the new Scientific Books.

(*Foreign Prices*).

14, HENRIETTA STREET, COVENT GARDEN, LONDON, & 20, S. FREDERICK STREET, EDINBURGH.

THE ELECTRICAL and GENERAL ENGINEERING COLLEGE and SCHOOL OF SCIENCE.

PENYWERN HOUSE

2, Penywern Road, EARL'S COURT, S.W.

Principal: G. W. de TUNZELMANN, B.Sc., M.I.E.E.

The Complete Courses qualify Students for entry into Electrical and other Engineering Work.

The First Year's Course is arranged to qualify for entry into Cooper's Hill, the Central Institution, and the Royal School of Mines.

Extensive Laboratories, Dynamo Room, &c.

Students are regularly sent to the College by leading Engineers and Scientific Authorities, whose names are given in the Prospectus.

Books for Electricians, Electrical Engineers, and Others.

Price 3s. 6d., post free.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT, M.I.C.E., M.I.M.E., &c. A Practical Treatise on the Steam-Engine Indicator and Indicator Diagrams, with Notes on Steam Engine Performances, Expansion of Steam, Behaviour of Steam in Steam Engine Cylinders, and on Gas Engine Diagrams.

320 pages, 155 illustrations, price 6s. 6d., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. LAWS, UNITS, AND SIMPLE MEASURING INSTRUMENTS. By A. E. KENNELLY and H. D. WILKINSON, M.I.E.E.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. KILGOUR. [*In preparation.*

With the extension of the heavier branches of Electrical Engineering the need of a publication of the Pocket-Book type dealing therewith increases; for while, on the one hand, there are many such referring to Mechanical Engineering, and, on the other hand, several which deal with Electrical Rules and Formulæ as more particularly applied to the lighter branches of Electrical Engineering, yet none of these alone suffice for the purposes of what may now be said to be the more numerous body of Electrical Engineering, viz.: those engaged in the application of Electricity to lighting, transmission of power, metallurgy and chemical manufacturing. It is to supply this want that this book has been prepared.

SUBMARINE CABLE-LAYING AND REPAIRING. An Original Work on this important subject, which has not previously been treated in a thoroughly practical manner. By H. D. WILKINSON, M.I.E.E., &c., &c. Fully illustrated. [*In preparation.*

ELECTRO-MAGNETIC THEORY. By OLIVER HEAVISIDE. [*In preparation.*

DRUM ARMATURE WINDING & COMMUTATORS: IN THEORY AND PRACTICE. By F. M. WEYMOUTH. [*In preparation.*

A complete treatise of the theory, and the different methods of construction of Drum Winding, and also of close-coiled continuous-current Commutators, together with a full resumé of some of the principal points of consideration that are involved in their design.

ELECTRICITY AS A MOTIVE POWER. By ALBION T. SNELL, Assoc.M.Inst.C.E., M.I.E.E. [*In preparation.*

ELECTRIC LIGHT: ITS PRODUCTION AND USE. By J. W. Urquhart. Fifth Edition, carefully revised, with large additions. Price 7s. 6d., post free (U.K.)

New Edition, 640 pages, 307 illustrations, price, cloth gilt, 10s. 6d., post free.

ELECTRICAL ENGINEERING FOR ELECTRIC LIGHT Artizans and Students. By W. Slingo and A. Brooker.

Second Edition. 358 pages, 126 illustrations, price, cloth gilt, 7s. 6d., post free.

ELECTRIC TRANSMISSION OF ENERGY, AND ITS TRANSFORMATION, SUBDIVISION, AND DISTRIBUTION. By Gisbert Kapp, C.E. A Practical Handbook

67 illustrations, price 6s., post free.

PRIMARY BATTERIES. By H. S. Carhart, A.M. Giving descriptions of the Construction, Working, and Testing of a large number of Primary Batteries, with Introductory Chapters on Theory.

Price 6s. 6d., post free.

A COMPREHENSIVE INTERNATIONAL WIRE TABLE. By W. S. Boult. Giving full particulars of 469 Conductors (4 gauges), Single Wires and Cables, in English, American, and Continental Units.

Fifth Edition, carefully revised, price 1s., post free.

THE ELECTRIC LIGHT POPULARLY EXPLAINED. By A. Bromley Holmes, M.INST.C.E.

Fourth Edition, revised and enlarged.

Cloth, 864 pages, 29 folding plates, 498 illustrations in text, 24s. post free.

DYNAMO-ELECTRIC MACHINERY: A TEXT-BOOK FOR STUDENTS OF ELECTRO-TECHNOLOGY. By Silvanus P. Thomson, B.A., D.Sc., M.I.E.E., F.R.S.

This edition has been very largely re-written, and contains several features distinguishing it from its predecessors. Detailed descriptions are given of the large dynamos used in central stations, and chapters are added on alternate-current motors, on the theory of armature winding, on the construction of armatures, commutators, &c., and on electrical transmission of power.

New and greatly enlarged Edition. Quarto, 300 pages, 275 illustrations, 12s. 6d., post free 13s. 6d.

THE ELECTRIC MOTOR AND ITS APPLICATIONS. By T. C. Martin and J. Wetzler.

A POCKET BOOK OF ELECTRICAL RULES AND TABLES, FOR THE USE OF ELECTRICIANS AND ENGINEERS. By John Munro, C.E., and Andrew Jamieson, C.E., F.R.S.E. Pocket size, leather. Ninth Edition, revised and enlarged, with numerous Diagrams. 8s. 6d.

With 227 illustrations, 3s. 6d., post free.

THE PRACTICAL TELEPHONE HANDBOOK AND GUIDE TO TELEPHONIC EXCHANGE. By Joseph Poole, Chief Electrician to the late Lancashire and Cheshire Telephonic Exchange Company, Manchester.

Fully illustrated, price 11s., post free.

THE ELECTRIC RAILWAY IN THEORY AND PRACTICE. By Oscar T. Crosby and Louis Bell.

This is the only *original* work on The Electric Railway published in any language. Other books are chiefly extracts from this valuable work.

For the Pocket. Price 2s. 6d.; post free, 2s. 7d

THE WIRING SLIDE RULE (TROTTER'S Patent).

By which can be found at once:—1. Size of Cable; 2. Length of Cable; 3. Current Cable will carry; 4. Current Density; 5. Maximum Current; 6. Resistance in Ohms; 7. Sectional Area in Square Inches.

Full Printed Instructions are supplied with each Rule.

INDIA RUBBER, GUTTA PERCHA AND TELEGRAPH WORKS CO.,

LIMITED.

ELECTRICAL ENGINEERS,

AND

INDIA RUBBER AND GUTTA PERCHA MANUFACTURERS.

MANUFACTURERS OF

CABLES, WIRES, INSTRUMENTS, INSULATORS, DYNAMO MACHINES, MOTORS, ARC LAMPS & FITTINGS, BATTERIES, CARBONS, TORPEDO APPARATUS.

SPECIALITY.—Underground Electric Light System for High and Low Tension. The only System which has given complete satisfaction.

Contracts entered into for the Erection and Equipment of Central Lighting Stations, the Lighting of Ships, Factories, Houses, and the Supply of Complete Plant for Electrical Traction and Transmission of Power.

VULCANISED INDIA RUBBER.

HOSE, DRIVING BANDS, STEAM PACKING, WATERPROOF GARMENTS and FABRICS, SHOE SOLES, MATS, VALVES, BRAKE BLOCKS, WHEEL TYRES for CABS, CARRIAGES, BICYCLES, &c. SHEET, WASHERS, BUFFERS, SPRINGS, TUBING, SOLID CORD, FOOTBALL BLADDERS, LAWN TENNIS BALLS. MOULDED GOODS to any Pattern.

EBONITE.

Not affected by Vinegar or Hydrochloric or Acetic Acid.

SPECIALITIES IN EBONITE FOR CHEMICAL WORKS.

INSULATORS, BATTERY CELLS, SPEAKING TUBES, SHEET & ROD, SURGICAL APPLIANCES, PHOTOGRAPHIC ARTICLES, SCREW STOPPERS, PUMPS.

GUTTA PERCHA.

TUBING, BELTING, BUCKETS, BOSSES for FLAX SPINNING, GOLF BALLS, SHEET and TISSUE.

Annual Subscription (U. K.), 19/6

NOTES.

The accounts of the City of London Electric Lighting Company, referring as they do to a concern still in the preliminary stage, do not present many points of general interest. The capital expenditure up to date is close on £450,000 out of a total received of £480,000. Lands and buildings account for £59,000 in round figures, and machinery of all sorts for £160,000; whilst the main laying operations of the past twelve months and more have cost over £127,000. A large and unique item is that of £57,782 9s. 6d. expended on "Conduits for Telephonic purposes." The Report states that eighteen transformer sub-station sites have been secured; these sub-stations are scarcely of Swinburnian dimensions, each one being of 20,000-light capacity.

As will be seen in another column the Coventry Town Council and Mr. Graff Baker have at last come to an agreement with regard to the electrical equipment of the tramway system of that ancient city, and we may anticipate that by the end of the present year the inhabitants of Coventry will be enjoying the full blessedness of the latest thing in tramways. We can only hope that "in the interests of the beautiful" the unredeemed ugliness of the trolley will be mitigated as far as may be.

Accustomed as are our local authorities to the respectful, not to say humble, tone of aboriginal electrical promoters, Mr. Graff Baker's *brusquerie* must have been a novel experience. The Works Committee wanted to know. They catechised Mr. Graff Baker, and ended up by requesting proof that he had paid £6,000 for the tramways, and that £35,000 had actually been expended on the lines. Now a mere Britisher would in all probability have immediately complied with this not unreasonable demand. Not so the purchaser of the Coventry Tramways. The Works Committee were berated as follows:—"The question of my having paid a certain sum for the line was settled when I stated, either verbally or in writing, that such was the fact, and a request for further proof borders on the insulting, more especially when the confirmation of anything I may have said in connection with this matter could easily be ascertained by any member of the Committee; and generally, the frivolous and trivial points that are raised are not worthy of consideration." However, "all's well that ends well," the "frivolous and trivial points" were considered and conceded and it was found possible to arrive at a satisfactory *modus vivendi*.

The effect of the earth currents due to the absence of an insulated return conductor on the City and South London Railway, to which we called attention a fortnight ago, seemed to be sufficiently serious, but we were quite prepared to learn that it was altogether eclipsed by American experience. The state of affairs in Cambridge, Mass., is recorded in our Notes. More remarkable, perhaps, than the five to ten volts between gas and water pipes on the same premises, is the complacency with which galvanised iron, rustless iron, brass, and lead pipes for the water supply were all tried in vain, the pipes lasting only from one to three months, and then giving way from electrolytic corrosion. The tramway company were notified that their return wires were not sufficiently large; though that, of course, was not so much the cause as that they were not insulated. The result was an overhead return wire. In another Note we record the electrolytic corrosion of water mains in Sault Ste. Marie (Mich.).

A full description of M. Blondel's arc standard of light, to which we referred last week, will be found in another column. Before it can be accepted either as a primary or as a secondary standard, some quantitative information should be given as to the effect of different kinds of carbon. It is not sufficient to learn that the values of the brilliancy sensibly agree. Before a negative result can be accepted, it is necessary, as Prof. Oliver Lodge recently pointed out in a short correspondence in *The Electrician*, to know something of the degree of accuracy with which the observations have been made. Photometry being, perhaps, the least accurate of all physical measurements, the so-called "probable error" is large—the expression, indeed, is a bad one, since the quantity is not probable and it is not an error. In the first place, then, we must learn the magnitude of the probable error in a number of comparisons of an arc with a certain kind of carbon, and these must be compared with the probable error of the whole series of observations. M. Blondel refers only to the general "experimental error." He alludes to it, however, only in connection with experiments with the Le Chatelier pyrophotometer, and we do not learn that any comparison has been made between different kinds of carbon used as arc-standards in the apparatus. For reasons into which we need not at present enter, we are inclined to doubt whether conclusions as to the photometric value of a naked arc can be drawn from results of observations with the Le Chatelier apparatus. The form of photometer shown in the illustration, the most elementary form of Bunsen photometer does not favourably impress us, but it is possible that the

Hosted by Google

representation is diagrammatic, though at the same time thoroughly realistic.

While anxious to hear both sides of controverted questions, and unwilling to suppress any author's views, even when they appear to be directly opposed to modern practice, we can, in some cases, only give him a hearing when, at the same time, we criticise or, at all events, call in question some of his contentions. The author may, then, well ask why his contribution should be printed if it fails to meet with approval; but in the case of the article by Mr. Sydney F. Walker which will be found in another column, the writer prefers that his views should be published as they stand, and he is ready to support them. The points which we cannot allow to pass without comment, are the assumptions that casing (or grooved boarding, as Mr. Walker calls it,) may be, and sometimes is, erected in a state in which it can readily absorb water, and that this will "undoubtedly destroy the insulation." In the first place, soft wood moulding is to be deprecated. The best class of work is always done with so-called white wood, and this should be well primed, or should have a thorough coating of knotting. Mr. Walker suggests the use of shellac. Not only is this expensive, but the thorough drying of the wood and the "filling of the pores" with this insulating material is more than can be expected from most contractors. Mr. Walker, in fact, admits that this "may not be the best substance to use on all conditions." What sort of insulation is this that will undoubtedly be destroyed by water? Surely wood casing is only intended for mechanical protection. If a little moisture is likely to do harm, and is to be rigidly excluded, why not go back to the old-fashioned impregnated jute covering? This is all right if moisture *is* excluded. Why should thousands of pounds be spent on high-class vulcanised rubber?

We fail to understand Mr. Walker's remarks about the earthing of an alternate-current circuit. He appears to imply that this cannot be done, because neither conductor "can be at zero when each is in turn positive and negative." We cannot understand his contention or his mode of reasoning, since in practice alternate currents may be, and are, deliberately earthed, and with most useful results. The old bugbear of bad joints in damp places is revived by Mr. Walker, and is adduced as an argument against concentric wiring. We believe that the author has experience in mining work, and in such cases, of course, special precautions are absolutely necessary; but in dealing, as he does, with the general question, it is sufficient to say that in the best systems of wiring, joints, as known in the old days, are the exception—at all events in house work—wires and the main cables themselves branching from distributing fuse boards.

University College, Bristol.—Courses on Civil, Mining, and Electrical Engineering will be held at this College during the Third Term, commencing April 25th.

Guildford.—The Urban Sanitary Authority has decided not to undertake an electric lighting scheme itself, but to allow a company to do so upon the usual terms as to purchase, &c.

Cable Interruptions and Repair—

Electrical Bills in Parliament.—On Thursday, the 30th ult., the Hampstead, St. Pancras, and Charing-cross Railway Bill was read a third time in the House of Commons.

The Proposed London University.—A scheme for the organisation of the proposed University for London was adopted at a general meeting of the Association for Promoting a Professional University for London on March 23rd, and has been submitted to the University Commissioners.

Gilbert's "De Magnete."—The following is a transatlantic review of Mr. Mottelay's translation:—"This work is valuable mainly on account of its history, and no doubt those who obtain a copy will derive a great deal of interest in reading its pages. It is bound in white cloth."

Copper Plating.—A method of coating steel with copper is now being developed in New York by Mr. W. B. Hollingshead. The copper is deposited on a sheet of steel by electrolysis, and the sheet is then rolled; after this a second coat of copper is deposited and the sheet rolled again. The deposit thus obtained is said to be firmly adherent.

Birkenhead.—At the monthly meeting of the Town Council the special Sub-Committee stated that it had fully inquired into the matter of electric lighting, and had come to the conclusion that the Corporation themselves should take steps, under the Birkenhead Electric Lighting Order, 1890, and proceed without delay to provide that light within the borough. The minutes of the Committee were confirmed.

The Electrical Utilisation of Water Power.—Next July the water-power station at Sémur, which will then be able to develop some 300 h.-p., will commence to supply current on the high-pressure alternating system to Saulieu, seventeen miles distant, Précy, nine miles distant, and Montbard, eleven miles distant. About 3,000 lamps will be connected. During the daytime current for power purposes will be supplied to the numerous tanneries surrounding Saulieu.

Copper.— Copper consumption has kept well ahead of supply in March, the "actual" deliveries in England and France amounting to 9,190 tons, and the arrivals to 6,591 tons. The quantities advised as afloat at the end of March are slightly in excess of those at the beginning of the month, so that the visible stock has only been reduced by 2,151 tons. This brings the stock down to about the figure at which it stood a year ago, when copper was worth £1 a ton more.

Kingston.—A Local Government Board inquiry into the application of the Kingston Town Council to borrow £16,000 for the purpose of lighting the borough by electricity was held on Wednesday last. The Town Clerk explained that the Corporation had entered into a provisional arrangement with the Surrey County Council to light their new buildings at Kingston with electricity by September next. It was proposed at present to provide 5,000 private incandescent lamps and 40 arc lamps for street lighting. There was very little opposition.

Snowstorms and Electric Tramways.—It is the custom just now to reduce as many things as possible to horse-power and cost, and the two following statements may, perhaps, serve as first approximations of the horse-power and cost of an American snowstorm:—A big storm in Ottawa recently required the electric railway to use 1,000 H.P. to keep the equipment in motion. The 250 miles of track operated by the Twin City Rapid Transit Company were buried under from 2ft. to 10ft. of solidly-packed snow during a storm in February last. The storm cost the Company about $10,000.

H.M.S. "Raleigh" Struck by Lightning.—The cruiser "Raleigh," flag-ship of Rear-Admiral Bedford, on the Cape of Good Hope station, has arrived at Simon's Town after an exciting experience at sea. The "Raleigh" had been on a cruise to the various ports around the West Coast, and after leaving Lagos for Fernandez Po, encountered a tornado. For

Hosted by Google

a time there was a continuous blaze of lightning overhead, and the rain fell in sheets. On the following day (Sunday) there was a renewal of the storm, and while the chaplain was conducting Divine service the ship was struck by lightning. It was afterwards discovered that the lightning had affected the ship's compasses.

Telephone Poles.—At a meeting of the Broughty Ferry Police Commission on Monday night last, a lengthy letter from the National Telephone Company was read, setting forth what they had done in the Ferry, and drawing attention to the great inconvenience that would result should the Company be compelled, in consequence of the Commissioners' demands, to close their Exchange. The Commissioners were obdurate, and resolved that the Clerk should be instructed to simply acknowledge receipt of the letter, and refer the Company to the notice ordering the removal of the poles in three months. The Committee appointed by the Commissioners had, it seems, suggested that the Company should give £2 per pole for each pole on the public streets, and 2s. per wire per annum. The Company would not entertain the idea of paying these sums.

Electrolytic Erosion of Water Mains.—The electrolysis of water mains by grounded circuits has been causing some trouble in Sault Ste. Marie, Mich. Dr. F. M. Taylor states in the *Engineering Record* that when the matter was discovered the Department of Public Works was much puzzled as to the cause, but having read that similar phenomena due to electricity had been noticed in other cities, he has become certain that the electric current was the cause of the leaks. The pipes were directly under the railway, and at a depth of about 6ft. The erosion was diffuse and irregular, the holes generally approximating an oval or elongated oval, with the longer axis parallel to the axis of the pipe. The eroded surface was very irregular, pitted, and bright as a new silver coin. The holes were at distances varying from a foot to 2½ft. apart, and on the upper surface. The deeper holes were directly under the rails on each side of the track.

"Installation."—"In the course of an interesting article on electrical nomenclature, brought out by the approaching World's Electrical Congress, *The Electrician* of London," says the *Western Electrician*, "takes occasion to express its disapproval of the word 'installation,' which it styles an 'affected and pompous term.' 'Plant,' 'job,' and 'work,' are mentioned as preferable words for the expression of this idea. We fail to see the force of our contemporary's objection. Even if the proposed substitutes were exact synonyms, which they are not, the only possible criticism of 'installation' would be the unimportant one that it is a polysyllabic word. Webster mentions 'to give a place to' as one of the definitions of the verb 'to install.' That is precisely what is done when an electrical plant is put in or installed, and it is entirely correct to refer to it thereafter as 'installation.' 'Plant' is driven to death, 'work' is awkward, and 'job' is inexpressive, so that 'installation' has an important and useful place."

Electric Traction at Coventry.—At the meeting of the Coventry Town Council on Thursday last week, the General Works Committee presented the following report:—"Your Committee herewith present the agreement which has been arrived at with Mr. Graff Baker with respect to the electrical equipment of the tramways, and beg to recommend that it be approved and sealed." The Mayor, in proposing the adoption of the report, said he thought it dealt finally with a long-standing dispute, and he ventured to say that it dealt with it very satisfactorily. The Council now saw the advantage of having postponed the matter from the last meeting of the Council, because they had had one or two alterations made which would be of advantage to the city. Although some of the members might not think this system the best they could have on account of its appearance, still he thought they had so modified its appearance that they could put up with it until something better presented itself. In that event a provision was made by which they could have an alteration. The report was then adopted.

Trade Advertisement at Technical Societies.—We never know, says *Industries*, quite how far the straightforward system of advertisement adopted in America is to be commended or condemned. For instance, we have just received a copy of a paper read before the American Institute of Electrical Engineers on "Micanite." It is a trade prospectus pure and simple, and is followed by a discussion. Recently, again, there was a paper on the Thomson joulemeter, or watt-meter as it is termed in the United States. In this country we have trade circulars too; but we frequently "assume a virtue when we have it not," and disguise the circular under a thin veil before bringing it before a scientific or technical society. When an English firm desires to push a new insulating material, made, say of mica and cement, or a meter which is devoid of any scientific originality whatever, one of its members reads a paper on "The Dielectric Properties of the Earth Silicates," or "Electrodynamical Means of Integrating Electrical Power," and their goods are thus advertised successfully. The American method is at least more straightforward, though perhaps less dignified.

Electrical Experiences in Minnesota.—Prof. G. D. Shepardson, of the University of Minnesota, gives an account of the electric condition of the atmosphere in Minnesota in the cold, dry weather. His bedroom, he says, has an ingrain carpet, from which he gets marked electrical shocks. On a cold morning he can hardly take a step without being strongly electrified. By shuffling across the carpet, taking only two steps, he has many times drawn a spark one-eighth of an inch long. By taking a dozen shuffling steps and touching the water faucet, he has several times drawn a spark nearly one-half of an inch long. "Indeed it is so common and so excessive that it is quite uncomfortable." It should be stated that this high degree of electrification is not an everyday experience, but it is very common when the thermometer in the room goes below 50 or 40 degrees Fah. A similar experience, says Prof. Shepardson, is very common when putting on a fur overcoat or one simply with a fur collar. The simple rubbing of the fur in putting on the coat will so electrify it that the wearer gets a prickly sensation from the charge from the collar when it is turned up against the neck.

The Birmingham Hydraulic Supply.—At a recent meeting of the Mason College Engineering Society, a Paper on "The Birmingham Hydraulic Supply Station" was read by Mr. Henry Lea. After a brief sketch of the history of modern water-pressure machinery, the author proceeded to describe the Birmingham Corporation Supply Station, which was engineered by Mr. J. W. Gray and Messrs. Henry Lea and Thornbery in conjunction. The station was opened in 1891, and the motive power is derived from Crossley gas engines. Mr. Lea described an arrangement of counters from which interesting figures were obtained, showing that although there is necessarily, at present, much idle running during which the machinery is not actually pumping into the accumulators, the efficiency of the plant is very high, the pumps delivering energy equal to about 60 per cent. of the indicated horse-power of the engines. When pumping continuously the efficiency is as high as 81 per cent. In the use of the high-pressure water for lifting purposes, the cost per ton lifted varies with the quantity of water used per quarter of a year, a sliding scale of charges being adopted; thus about 12 cwt. or eight persons can be raised 40 feet for 1d. when the minimum quantity per quarter is used, and about 3 tons, or, say, 40 persons to the same height when the maximum quantity is used.

Electric Traction and the Earth Return.—The *Street Railway Review* recently circularised the street railways companies of the United States with a view of ascertaining the general drift of opinion on the "ground return" question. The following statements are worthy of notice:—Mr. Charles H. Morse, superintendent of the fire alarm and police telegraph systems of Cambridge, Mass., has found that in various parts of Cambridge the currents of the West End Railway Company, escaping to the water and gas pipes, have prematurely corroded these pipes. Accordingly in April last he notified the West End Company that its return wires were not sufficiently large, and the Company then began to put in overhead return wires upon its principal lines. About two months ago water pipes near the Company's power house in East Cambridge began

Hosted by Google

to show leaks. The matter was investigated, and the pipes showed electrolytic action. It appeared that galvanised iron, rustless iron, brass, and even lead pipes had all been tried in vain. Pipes would last only from one to three months, irrespective of the kind. Since then chip-stone and drain pipe have been successfully used to protect the metal pipes from the action of the currents. Mr. Morse states further that he made some surprising discoveries. For example, a number of tests showed a difference of potential of over 40 volts between water pipes in East Cambridge and Cambridgeport. In some parts of the city, water and gas pipes on the same premises showed from 5 to 10 volts difference in voltage. Workmen relaying pipes have seen arcs formed at the joints, and in some instances the current has actually set fire to the hemp packing used in the joints.

Electric Signalling from Captive Balloons.—At a recent meeting of the Royal United Service Institution Mr. Eric S. Bruce delivered a lecture on "Electric Balloon Signalling." The lecturer observed that to obtain altitude for signalling was a decided advantage. Some few years ago it occurred to him to so apply electric flash signalling to a captive balloon that the operator and most of the apparatus might remain on the ground. Several incandescent electric lamps were placed in the interior of the balloon made of a material that was translucent and filled with pure hydrogen or coal gas. By varying the duration of the flashes signalling could take place according to the Morse or any other code. Concerning the chances of a balloon being hit by the enemy, he stated that experiments which took place at Lydd and in Germany had shown that it was almost impossible to hit a balloon until its distance and height were known, while with regard to small-arms fire the damage done by occasional bullets could easily be repaired. Wind was usually considered the bugbear of captive balloons, but his experience with these balloons was that even in our breezy island they could ascend successfully and usefully on a large average of days in the year. The lights in the balloon could, if desired, be turned on continuously, and this continuous illumination had its uses. It would be valuable as a preconcerted signal or as a point light to concentrate troops at night to a given place. Observations and criticisms upon the invention were afterwards made by Lieutenant Baden-Powell, Admiral Colomb, Commander Lionel de L. Wells, Colonel Thackeray, Colonel Keyser (Inspector of Army Signalling), Admiral Sir William Dowell, and others.

Mr. Preece on Lightning Protection.—The editor of *Nature* has been good enough to forward us an advance proof of the following letter:—

In the recent Presidential address to the Institution of Electrical Engineers by Mr. Preece I find the following reference to myself: "Prof. Oliver Lodge has . . . endeavoured to modify our views as to the behaviour of lightning discharges, and as to the form of protectors, but without much success. His views have not received general acceptance, for they are contrary to fact and to experience." I was quite prepared to laugh at this with the rest, but I find that the general and semi-scientific public are apt to take Mr. Preece's little jokes, of which there are many towards the end of this address, as serious and authoritative statements of scientific fact. And it has been represented to me that unless I take some notice of the above, it may be assumed that I wish silently to withdraw from an untenable position without acknowledging having made a mistake. Indeed, I have already been questioned by a scientific worker as to whether I accepted the above statement as in any sense corresponding to truth. My reply is, that so far was I from that attitude that I did not suppose that the statement was either meant or would be taken seriously. The broad question of scientific fact is this:—Given an electrostatic charge at high potential, can the potential be reduced to zero most quietly and safely by a good conductor or by a bad one? The old lightning-rod doctrine (or drain-pipe) theory said, by an extravagantly good one. I say, by a reasonably bad one. If you employ too good a conductor the mean square of current is appallingly strong, and all manner of dangerous oscillations are set up; whereas in a bad conductor the discharge can be more nearly dead-beat. These oscillations have been experimentally and mathematically demonstrated in a great variety of ways, the unexpected and distinct effects they are able to produce have been displayed, and Messrs. Whittaker have published for me a large book about them. Some critics have sensibly objected that the book is too big, but I am not aware of any scientific authority who controverts my position. If Mr. Preece only means that these views regarding lightning and its dangers are not yet practically accepted by the great British Telegraphic Department, that is, I admit, perfectly true.—OLIVER LODGE.

Electricity on Warships.—In a recent Paper on "The Transmission and Distribution of Power in Modern Ships," Signor Nabor Soliani, of the Italian Admiralty, discusses the pros and cons of electric power. He points out that the erection of electrical circuits offers but little difficulty, the wires being easily bent as desired, easily passed through anywhere, and easily joined again in case they should break. Electric motors neither radiate heat nor leak hot water, and the manipulation of a switch is sufficient to start, accelerate, slacken, or stop the movement of the motor. On the other hand the disadvantage of the high speed of motors which either greatly limits their utilisation or involves cumbersome gearing is insisted on, as is also the difficulty of locating faults in electric circuits Electric circuits are moreover very liable to suffer from inrushes of water. Finally, electric-motors are not very well adapted for machinery designed to operate, for instance, the rudder, the anchor, &c., in which the resistance to be overcome might suddenly change, resulting in an enormous rush of current, damaging alike to generator, motor, and conductor. Signor Soliani is, therefore, inclined to think that, upon the whole, the area of electrical applications on board ship is not so extensive as it might at first sight appear, and that great improvements must be made before electricity can supersede those other means which are now used for the transmission and distribution of power. He further points out that at present a very low potential of only 65 volts is used, which, for electric lighting, is suitable; but would no longer be adequate in the case of a general system of transmission and distribution, on account of the enormous current which it would be necessary to transmit.

The Elevated Electric Railway at the Chicago Exhibition.—The general public, as well as railway men and members of the electrical fraternity, are much interested, says the *Western Electrician*, in the elevated electric railway now nearing completion at the World's Fair grounds. The line is being constructed by the Western Dummy Railroad Company, which is merely an offshoot of the General Electric Company. The line is three and one-tenth miles long, double tracked, with loop terminals. The foundations for the structure are generally concrete, 7ft. by 7ft, and one foot deep, placed about 4ft. below the surface of the ground. The spans are generally 25ft. The lowest part of the structure allows 12ft. head room, and in the highest 27ft. The gradients have been designed as far as possible to allow an ascending gradient approaching each station. The heaviest gradient is 1½ per cent. The boiler house contains 10 300-H.P. Babcock and Wilcox boilers. Oil will be burned as fuel. The engine room contains a 2,000-H.P. Reynolds-Corliss cross compound condensing engine, coupled direct to a 1,500-kilowatt Thomson-Houston multipolar generator. This dynamo is the largest on the World's Fair grounds. The armature shaft alone weighs 65 tons. It is of solid steel, 24in. in diameter. At one end of the building is a 750-H.P. Reynolds cross compound engine coupled direct to a 500-kilowatt Thomson-Houston multipolar generator with an over-hung armature. Midway between this engine and the largest engine is located a 750-H.P. Hammond-Williams compound, condensing, vertical engine, coupled direct to a 500-kilowatt Thomson-Houston multipolar generator. At the other end of the engine room there is a 750-H.P. tandem cross compound condensing Greene engine, belted direct to a 500-kilowatt Thomson-Houston multipolar generator. Between the Greene engine and the Allis engine is placed a 400-H.P. tandem compound condensing engine, coupled direct to a 200-kilowatt Thomson-Houston multipolar generator. The rolling stock will consist of about eighteen trains, each consisting of four cars, the first car in each train being equipped with four motors. The motors have a nominal horse power of about 133 each, making a total of 532 to each train. The cars are to be controlled on the series-parallel principle, the motors being placed in series at the start and gradually thrown into parallel. The cars are equipped with air brakes of the latest design, they are 47ft. long, and will seat 96 people. The conductor for carrying current from the power station to the trains consists of a 60-pound steel T rail, mounted on insulated blocks and placed outside the track. The current is carried from this rail to the car by means of a sliding copper shoe, which rests on the top of the rail and is held in contact with it by a spring. The current is returned through the iron structure.

ELECTROMAGNETIC THEORY.—XLVII.

BY OLIVER HEAVISIDE.

(*Continued from page 594.*)

§ 193. Coming now to the effects produced on electromagnetic waves by a small amount of conductivity, to be afterwards increased, we shall adopt a particular device for simplifying the treatment. Imagine, first, the dielectric medium to possess a uniformly-distributed small conductivity. Evidently, the action of the conductivity on a wave is a continuous and cumulative one. Next, localise the conductance in parallel sheets—that is, substitute for the uniform conductivity a great number of parallel plane conducting sheets, between which the medium is non-conducting. If we increase their number sufficiently, their action on a wave whose plane is parallel to that of the sheets will approximate, in the gross, to the effect of the uniform conductivity which the conductance of the sheets replaces. We have, therefore, to examine the influence of a single very thin conducting sheet upon a wave. This is not difficult.

Imagine, then, a simple plane electromagnetic sheet to be running through the ether at the speed of light. This is the natural state of things; and, in the absence of conductivity or other disturbing causes, there will be no change. Now insert a plane conducting sheet in the path of the wave. It should be so thin that the retarding effect of diffusion within it is quite insensible. Let the wave strike it flush. The theory shows that it is immediately split into two similar waves, one of which is transmitted beyond the plate, whilst the other is reflected. The transmitted wave differs from the incident in no respect except strength. It is attenuated in a certain ratio depending upon the conductance of the sheet, being greatly attenuated when the conductance is large, and slightly attenuated when it is small. The formulæ are reserved. This transmitted wave moves on just as the incident wave did, and nothing further happens to it. The reflected wave, on the other hand, having its direction of motion opposite to that of the incident and transmitted waves, travels back the way it came, and nothing further happens to it.

The direction of the magnetic force in the three waves is the same. This is one general property, irrespective of the amount of conductance. But a much more striking one connects the intensity of the magnetic force in the three waves. The sum of the intensities in the reflected and transmitted waves equals the intensity in the original incident wave. That is, the conductance, with dissipation of energy, has had no effect whatever on the total induction. It has merely redistributed it, by splitting it into two parts, which then separate from one another. The "number of tubes" in the reflected wave may be made to bear any ratio we please to the number in the transmitted wave by altering the conductance of the plate; but their sum is always exactly the number of tubes in the incident wave. This property exemplifies, in a manner which may be readily understood, the persistence of induction, in spite of conduction and waste of energy.

But as regards the displacement, the case is quite different. From the fact that the reflected wave runs back, whilst its magnetic force preserves its original direction, we see that the electric force must be reversed. On the other hand, it is unchanged in the transmitted wave. If, then, their sum equalled the electric force in the incident wave, it would imply that the transmitted wave was of greater amplitude than the incident. But it is smaller, invariably. So there is a loss of displacement. Thus, if H in the incident becomes $(1-n)$H in the transmitted wave, where n is some proper fraction, it becomes nH in the reflected wave. At the same time E in the incident becomes $(1-n)$E in the transmitted, and $-n$E in the reflected wave. The loss of E is, therefore, $2n$E, or the loss of displacement is $2n$D. By the loss we mean the excess of the displacement in the incident over the sum of the displacements in the two resulting waves, transmitted and reflected. This loss occurs at the very moment the incident wave coincides with the plate. The plate itself may be regarded as a dielectric homogeneous with the ether outside, or perhaps of different permittivity, but with the conducting and dissipating property superposed. When thin enough, the permittance of the plate is of insensible influence, and may be disregarded. But strictly, a conducting dielectric is a dielectric which cannot support displacement without wasting it, so that a continuous supply of fresh displacement is needed to keep it up. The rate of waste of energy is proportional to the electric stress.

But it should be carefully noted that the loss of energy and the loss of displacement are entirely distinct things, which are not proportional; and that the loss of displacement itself may sometimes require to be understood in a somewhat artificial sense. For the loss may be greater than what there is to lose. It must then be understood vectorially. This occurs when n is greater than $\frac{1}{2}$. When $n=\frac{1}{2}$, the reflected and transmitted waves are equally strong, and only differ in the direction of the displacement. The loss of displacement is, therefore, complete. The loss of energy in the plate is simultaneously at its maximum, being equal to one-half of the energy of the original wave. If we reduce the conductance of the plate, we increase the transmitted wave, and reduce the waste of energy in it and the loss of displacement. The amount of the latter still remains positive, therefore, assuming it to be positive in the incident wave. The extreme is reached when the plate has no conductance. Then the incident wave goes right through without any splitting and reflection, and therefore without attenuation, and there is no waste of energy. On the other hand, if we increase the conductance above the critical value making $n=\frac{1}{2}$, we reduce the transmitted wave and increase the reflected, whilst we simultaneously reduce the waste of energy in the plate and increase the loss of displacement. The extreme is reached when the plate is a perfect conductor. There is then no transmitted wave and no loss of energy, whilst the reflected wave is of full size, but with the displacement reversed as compared with the incident, so that the loss of displacement, in the sense described, is the greatest possible, viz., 2D.

It will be seen from these details that whilst the absorption or dissolving of induction by conductance is a myth, the idea of an absorption of displacement is not without its inconveniences when the conductance is great, and that this becomes extreme when there is really no loss of energy in the plate, when, in fact, the incident wave does nothing in it, but is wholly rejected with its displacement reversed. It seems, then, more natural to consider the waste of energy from the field caused by the plate as loss. This takes place equally from the electric and magnetic energies, since they are necessarily equal in every one of the three waves. But in the application made later, the plate is to have very slight conductance (in the limit an infinitely small amount), so that the total displacement cannot change sign, but merely suffers a slight loss. Then the idea of loss of displacement by conductance becomes useful again.

The loss of energy takes place as the incident wave is traversing the plate. Its successive layers each cause a minute attenuation of the wave passing, and this applies equally to the induction and displacement, so that the transmitted wave emerges from the plate a pure electromagnetic wave, a reduced copy of the incident. The successive layers, too, each cast back a minute portion of the wave traversing them, with unchanged sign of the induction, but with displacement reversed; and these rejected fluxes make up the reflected wave. There are evidently residual effects due to the internal reflections of minute portions of the main reflected wave, but these residuals tend to vanish when the plate is thin enough.

If the plate be a magnetic instead of an electric conductor, the theory is quite similar. The transmitted wave is an attenuated continuation of the incident. The reflected wave is also a copy of the incident, also reduced. But it is now the induction that suffers loss, because its direction in the reflected wave is opposite to that in the incident and transmitted. On the other hand, the displacement now fully persists, being merely split into two parts by the plate.

Notice that if the plate be both an electric and a magnetic conductor, its attenuating effect from these two causes on the transmitted wave will be additive, so that it will emerge a pure wave with extra attenuation. But as regards the reflected wave, we have a peculiar result. The action of the magnetic

Hosted by Google

conductance is to reverse the induction whilst keeping the displacement straight; whilst that of the electric conductance is to reverse the displacement and keep the induction straight. The result is that the reflected wave is reduced in magnitude by the addition of magnetic conductance to previously existent electric conductance. With a proper proportioning of the two conductances, the reflected wave may be brought nearly to evanescence from a plate of finite conductance. In the limit the compensation is perfect, and the incident wave goes right through without reflection, though it suffers extra attenuation. This is the explanation of the distortionless propagation of waves in a dielectric medium possessing duplex conductivity, electric and magnetic. Whilst there is no reflection in transit, there is a continuous loss both of displacement and of induction.

§ 194. Now return to the case of electric conductivity alone, and, as described, let it be locally condensed into the conductance of any number of parallel plates. We know that the effect of any one of them on a thin electromagnetic sheet is to split it, as previously described. If we like, therefore, we can follow each of the resulting waves, and observe how they are, in their turn, split by the first plates they meet, giving rise to four waves, to be a little later split into eight, and so on. This process may seem cumbrous, but it is also an instructive one.

Thus, consider what happens to the total induction. We know that it persists in amount and direction when a single split occurs. Now the same property applies to every successive split a wave suffers in our dielectric medium containing parallel conducting plates. So the total induction remains constant. It is redistributed and spreads out both ways, but without the least loss. There is a small loss of energy at every split, but this does not affect the total induction. This applies when we start from a single pure electromagnetic sheet moving either way. It therefore applies when the initial state consists of any number of such sheets, of any strengths, forming a perfectly arbitrary initial distribution of induction and displacement in parallel plane layers. There is still persistence of the induction. Finally, the same applies when we split up the conducting plates themselves into plates of smaller conductance, and spread them out at uniform distances. The ultimate limit of this process is reached when the conductance is quite uniformly spread, so that we have a perfectly homogeneous medium under consideration. It is, fundamentally, a dielectric propagating disturbances at speed v; but it is, in addition, a conductor as well and distorts the waves and dissipates their energy. The speed v is $(\mu c)^{-\frac{1}{2}}$, with the proper values of μ and c. The conductivity does not interfere with this property of propagation at finite speed. But observe that if we choose to ignore the displacement, then the corresponding speed is infinitely great. We conclude from the above that plane sheets of induction in electric conductors always preserve the total induction constant in amount, irrespective of the amount of elastic displacement, or whether there is any at all. That is, induction cannot be destroyed by conductance.

If then, it suffers destruction, this must be due to some other cause. It may be merely a cancellation by the union of oppositely-directed inductions. This may be termed a vectorial cancellation. It may occur, of course, with plane strata of induction. Thus if, in an infinitely large conductor, the total induction be initially zero, which does not require the induction density to be zero, the final effect will be a complete annihilation of the induction by mutual cancellations. Should, however, the total induction be not zero, it will persist. The induction density will tend to zero, but that will be merely on account of its attenuation by spreading, not because there is any destruction by the conductance or resistance when either of them is finite. To prevent the attenuation to zero we may interpose infinitely conducting barriers, one on each side, in planes parallel to the sheets of induction. Then the final result will be that the induction will spread itself out uniformly between the barriers and maintain a finite density.

To illustrate this property in a somewhat less abstract manner, consider a large ring, say of copper, though iron will do equally well except as regards some complications connected with its magnetisation. Let it be inductised by an enveloping coil-current so that the induction goes along the core in a complete circuit. When it is steadily set up, if we remove the coil-current (and the coil too, preferably for our present purpose) the induction in the core will, in time, all come out of it. But if we clap an infinitely-conducting skin upon the core, it will not come out. Then we have a certain flux of induction locked up, as it were, in a conducting material, which has no effect upon it. It can neither be destroyed by the conductance of the core nor can it get through the perfectly-obstructive skin. If the skin is clapped on after the induction has partially escaped (which escape begins on the outside, before the interior is sensibly affected), there is a redistribution of induction, which continues until a new state of equilibrium is reached. During this process there is electric current in the core and some waste of energy. But there is no waste of the induction. The final induction is the mean value of the original induction across the section of the core.

In further illustration, let the core be hollow and be inductised circularly—instead of along its length—by means of two currents on its boundaries, inner and outer, oppositely directed, following the length of the core. When this is done, remove the currents and clap on perfectly conducting skins internally and externally. There will be a similar persistence of the induction, although its tubes now go round the inner boundary circularly. There may be an initial settling down, but the outer skin will not let the induction expand outwardly, and the inner skin will not let it contract inwardly. If the latter could happen we might have cancellation. To get this effect remove the inner skin. Then, whether we fill up the hollow with finitely conducting matter or leave it nonconducting, we allow the induction to spread internally and permit cancellation. The induction will now wholly disappear, in spite of the external skin. That is to say, there will be a continuous passage of the induction out of the initially inductised region, accompanied by electric current therein, which will continue until the whole of the magnetic energy is wasted as heat in the core.

The same property is exemplified, though in a less easily understandable manner, with a single closed line or circuit of infinite conductance. If it embrace a certain amount of induction it will always do so, in the absence of impressed force to alter the amount. The induction is locked in and cannot pass through the infinitely-conducting circuit to dissipate itself. If the conductance of the circuit be finite, then it can get through. The time-constant varies as the conductance. The disappearance of the induction is manifested by the waste of energy in the circuit, the electric current in which is supported by the voltage of the decreasing induction through it. But the current is there all the same (measured magnetically) when the conductance is infinite. The induction is steady, and there is no voltage in the circuit. But none is needed.

On the other hand, if there is initially no induction through the circuit, there will continue to be none when the magnetic field is created in its neighbourhood. But although the tubes of induction cannot cut through the infinitely conducting circuit so as to make the induction through it be a finite quantity, yet they do pass through a surface bounded by the circuit, as much positively as negatively. The resulting induction distribution is to be got by superimposing the external induction and that due to a current in the circuit of such strength as to make the total induction through it be zero. The property is a general one, for if the circuit be moved about in a magnetic field, there will always, in virtue of its impermeability to the magnetic flux, be zero total induction through it if its conductance be infinite; whilst if it be finite but great, there is an approximation to this result so long as the motion is kept up, or the external field be kept varying. At the same time, the least amount of resistance in the circuit will be sufficient, if time enough be given, to allow the external induction, when due to a steady cause, to get past it to the full extent, when of course the current in the circuit will cease.

In a similar manner, displacement can be locked up by a circuit of perfect magnetic conductance. There is also persistence of displacement in spite of a finite degree of magnetic conductivity in a continuous medium, unless it be electrically conducting as well.

(To be continued.)

ALTERNATING CURRENTS AND ROTARY FIELDS.

BY ALEX. RUSSELL.

As the recent improvements in alternate-current motors ensures for them a large and increasing use in the near future, it is important that engineers should have a good working knowledge of the action of alternating currents of electricity. To obtain this an elementary knowledge of trigonometry and mechanics is quite sufficient.

An alternating electric current is one that flows for a small fraction of a second in one direction, and then, for an equal time, in the opposite direction, these changes in the direction of the flow taking place many times in a second.

A good way of picturing to the mind the instantaneous values of an alternating current is to consider a point P (Fig. 1) revolving round a circle whose centre is O, and whose radius O P is the maximum value of the current which we shall denote by I. Then, if we draw a perpendicular P N on a fixed diameter A A′ of the circle, we can represent the current by the line O N, the current being positive when N is to the right of O and negative when N is to the left. If the point P goes n times round the circle in a second, then the *frequency* of the alternating current is n. The *period* of the alternating current is the time P takes to make one revolution. It evidently is equal to $1/n$.

The *phase* of the current O N is the angle P O A, or it may be defined as the fraction of the whole period that has elapsed since the current last had its maximum positive value.

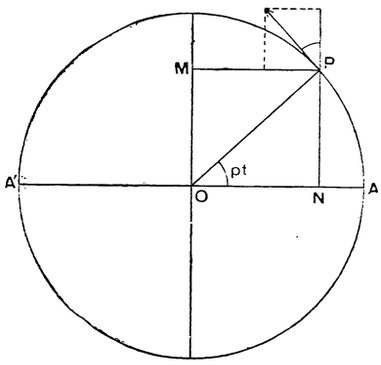

FIG. 1.—As P rotates round the Circle, O N represents the Instantaneous Value of the Current.

In general, the speed of P varies in one revolution and depends on the phase of the current, but we can arrive at approximate and very useful results by considering the speed of P to be constant and equal to its mean speed. Since the circumference of the circle is 2π I, the mean speed of P is $2\pi n$ I, remembering that speed is measured by the number of units of space described per second. If i represent O N, the instantaneous value of the current at the time t, then $i = \mathrm{I}\cos$ P O N. Now the circular measure of the angle P O N is $\frac{\text{arc}}{\text{radius}} = \frac{2\pi n \mathrm{I} t}{\mathrm{I}} = 2\pi n t = p t$ (say). Hence $i = \mathrm{I}\cos p t$.

If we measure the current by an alternating current ammeter, what we measure is the square root of the mean square of the current. We shall first consider what is the value of the mean square of the current. By a well-known formula in trigonometry,

$$\mathrm{I}^2\cos^2 p t = \tfrac{1}{2}\mathrm{I}^2 - \tfrac{1}{2}\mathrm{I}^2\cos 2 p t.$$

Now, for a complete period the mean value of $\frac{1}{2}\mathrm{I}^2$ is $\frac{1}{2}\mathrm{I}^2$, since I does not vary with t, and the mean value of $\frac{1}{2}\mathrm{I}^2\cos 2 p t$ is zero, since there are as many negative as positive values. Therefore the mean value of i^2 is $\frac{1}{2}\mathrm{I}^2$. If A be the direct current which would give the same reading on the ammeter, then $\mathrm{A} = \sqrt{(\frac{1}{2}\mathrm{I}^2)} = 0{\cdot}707\,\mathrm{I}$. A may be called the effective value of the current.

In a circuit a direct current does not instantaneously rise to its maximum value, owing to the self-induction of the circuit. The effect of self-induction is to bring into existence a counter E.M.F., whose magnitude is directly proportional to the rate at which the current O N changes. In other words, this E.M.F. equals some constant multiplied by the rate of change of O N. This constant is defined to be the coefficient of self-induction of the circuit. We shall denote it by L.

Then E.M.F. of S.I. $= \mathrm{L} \times$ rate of change of O N,
$= \mathrm{L} \times$ velocity of N,
$= \mathrm{L} \times$ horizontal component of vel. of P,
$= \mathrm{L} \times 2\pi n \mathrm{I} \sin$ P O N,
$= \mathrm{L} p \mathrm{I} \sin p t.$

As the current is diminishing this E.M.F. is positive. If e be the applied E.M.F. and R the resistance of the circuit, we obviously have, by Ohm's law,

$$\mathrm{I}\cos p t = \frac{e + \mathrm{L} p \mathrm{I} \sin p t}{\mathrm{R}};$$

$$\therefore e = \mathrm{R}\,\mathrm{I}\cos p t - \mathrm{L} p \mathrm{I} \sin p t,$$

$$= \sqrt{\mathrm{R}^2 + \mathrm{L}^2 p^2}\,.\mathrm{I}\left\{\cos p t.\frac{\mathrm{R}}{\sqrt{\mathrm{R}^2 + \mathrm{L}^2 p^2}} - \sin p t.\frac{\mathrm{L} p}{\sqrt{\mathrm{R}^2 + \mathrm{L}^2 p^2}}\right\}$$

$$= \sqrt{\mathrm{R}^2 + \mathrm{L}^2 p^2}\,\mathrm{I}\cos(p t + \alpha),$$

where $\tan\alpha = \mathrm{L} p/\mathrm{R}$.

Thus the phase of the E.M.F. is in advance of the phase of the current. The effect of self-induction is, therefore, to make the phase of the current lag behind the phase of the E.M.F. by an angle whose tangent is $\mathrm{L} p/\mathrm{R}$. We shall now consider what happens when a condenser C is put in the circuit. If Q be the quantity of electricity in the condenser at any instant, then we know by the definition of current that the rate at which Q is stored up in the condenser is equal to $\mathrm{I}\cos p t$. But from the figure the rate at which $\mathrm{I}\sin p t$ (O M) increases with t is equal to the vertical velocity of P is equal to $p\,\mathrm{I}\cos p t$. Hence the rate at which $\mathrm{I}/p \sin p t$ increases with t is equal to $\mathrm{I}\cos p t$. Therefore, $\mathrm{Q} = \mathrm{I}/p \sin p t +$ some constant. If $\mathrm{Q} = 0$ when $t = 0$, $\mathrm{Q} = \mathrm{C}\,\mathrm{E}' = \mathrm{I}/p \sin p t$, where E′ is the potential difference between the terminals of the condenser. Thus, $\mathrm{E}' = \mathrm{I}/c p \sin p t$.

Hence, if we have a circuit having self-induction and capacit in series,

$$\mathrm{I}\cos p t = \frac{e + \mathrm{L} p \mathrm{I}\sin p t - \mathrm{I}/c p \sin p t}{\mathrm{R}},$$

$$\therefore e = \mathrm{I}\{\mathrm{R}\cos p t - (\mathrm{L} - 1/c p^2)\, p \sin p t\},$$

$$= \mathrm{I}\sqrt{\mathrm{R}^2 + (\mathrm{L} - 1/c p^2)^2 p^2}\cos(p t + \beta),$$

where $\tan\beta = \dfrac{(\mathrm{L} - 1/c p^2) p}{\mathrm{R}}$.

The form of this result shows us that the presence of the condenser is the same as if we had a resistance coil whose resistance was zero and coefficient of self-induction $-1/c p^2$. If we put both R and L equal to zero in the last formula, we see that the phase of the current is in advance of the phase of the E.M.F. If we had n condensers, $c_1\, c_2 \ldots \mathrm{C}_n$, in series, they would act like a resistance coil $[0, -1/c_1 p^2 - 1/c_2 p^2 - \ldots]$. It follows that the n condensers act like a single condenser whose capacity is C, where

$$1/\mathrm{C} = 1/c_1 + 1/c_2 + \ldots + 1/c_n;$$

a well-known theorem in statical electricity.

We have still to show how alternating currents of the same period combine.

Let O L, O M (Fig. 2), represent instantaneous values of two currents, whose phase difference is the angle A O B, O A and O B being the maximum values of the currents. Describe a parallelogram on O A and O B as adjacent sides, and let O R be its diagonal; then, if we draw R N at right angles to O X,

$$\mathrm{O\,N} = \mathrm{O\,L} + \mathrm{L\,N} = \mathrm{O\,L} + \mathrm{A\,K} = \mathrm{O\,L} + \mathrm{O\,M}.$$

Hence O N, which is equal to the sum of the currents O L and O M, is their resultant, and the maximum value of this resultant current is O R. If there had been a third current O C, the resultant of the three would be determined by the diagonal of the parallelogram described on O R and O C as adjacent sides, and so on for any number of currents. Since the effective values of the alternating currents are proportional

Hosted by Google

to their maximum values, their resultant is found in the same way. For example, suppose the effective values of the currents in a divided circuit are A′ and A″, and their difference of phase is α. Construct a parallelogram, the lengths of the adjacent sides being A′ and A″, and α being the angle between them; then the length A of the diagonal of this parallelogram gives us the effective value of the main current, and the phase differences between the currents are given by the angles between the sides and diagonal of this paralellogram. Conversely, if we are given the main current and the phase differences, we can find the branch currents by this parallelogram construction.

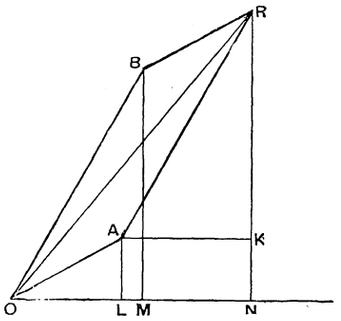

FIG. 2.—Method of Compounding Alternating Currents.

When a direct current A′ and an alternating current i are superposed, the instantaneous value of the current is $A'+i$. To get the reading on an ammeter in the circuit, we have to consider the mean value of $(A'+i)^2$ for a period. Now, $(A'+i)^2 = A'^2 + 2A'i + i^2$, and the mean value of this expression is $A'^2 + A^2$, for $2A'i$ has as many positive as negative values. Hence, the reading on the ammeter is $\sqrt{A^2 + A'^2}$, A being the effective value of the alternating current.

The reading on the ammeter would be the same, if, instead of a direct current A′ and an alternating current A, we had two alternating currents A and A′, whose phase difference was 90deg.

Exactly similar theorems hold for compounding alternating E.M.F.s. If an alternating E.M.F. has a maximum value E, then the effective value $V = 1/\sqrt{2}\,E = 0{\cdot}707\,E$; and if the potential difference between the terminals of an electrostatic voltmeter be $V' + E\cos(pt+\alpha)$, then the reading on the voltmeter is $\sqrt{V^2 + V'^2}$.

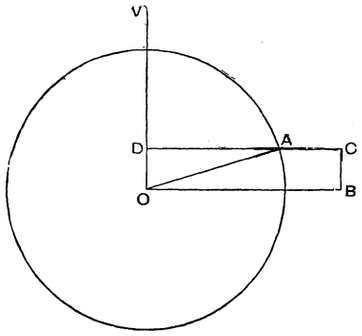

FIG. 3.—The area of O B C D measures the Watts in the Circuit.

To measure the power expended in an alternating-current circuit is not a simple matter, since the phases of the E.M.F. and current are different.

If the current is $I\cos pt$ we have seen that the E.M.F. is of the form $E\cos(pt+\alpha)$.

At any instant, therefore, the watts expended on the circuit

$$= E\,I\cos pt\cos(pt+\alpha),$$
$$= \tfrac{1}{2}E\,I\,\{\cos\alpha + \cos(2pt+\alpha)\},$$
$$= \tfrac{1}{2}E\,I\cos\alpha + \tfrac{1}{2}E\,I\cos(2pt+\alpha).$$

The mean value of this for a complete period is $\frac{1}{2}E\,I\cos\alpha$, for the mean value of $\frac{1}{2}E\,I\cos(2pt+\alpha)$ is zero. The watts being expended on the circuit are therefore $V\,A\cos\alpha$, where V and A are the readings on the voltmeter and ammeter respectively. Graphically, if O V (Fig. 3) = V, the angle V O A = α, O A = A, and we draw O B at right angles to O V and = V, the work done is equal to the area of the rectangle O B C A D. From the diagram we can see that a given error in measuring α produces a larger percentage error in our determination of the power, the greater the angle α is.

The production of rotary fields by means of ordinary alternating currents is a problem of great practical utility. A rotary field for experimental purposes when we have an alternating current supply can be made very simply. Take a few thin strips of sheet iron and bend them into a circular

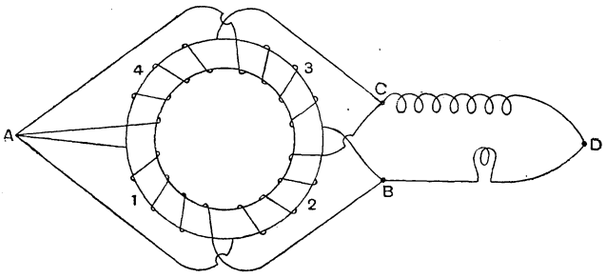

FIG. 4.—Experimental Rotary Field.

hoop. Now coil wires round this hoop as in Fig. 4. Connect C to a choking coil, and B to an incandescent lamp, the currents in each being equal. If we now connect A and D to the supply mains we get a rotary field inside the ring. Compass needles and discs of iron pivoted on pins placed inside this ring will revolve with great rapidity. To reverse the direction of rotation we connect the choking coil on to B and the lamp on to C the rotating bodies inside the ring will now rotate in the opposite direction. The reason of this can easily be seen graphically by drawing the magnetic state of the ring at various instants due to the magnetising currents round it.

The current that flows through the lamp is nearly in the same phase with the applied E.M.F., because the self-induction

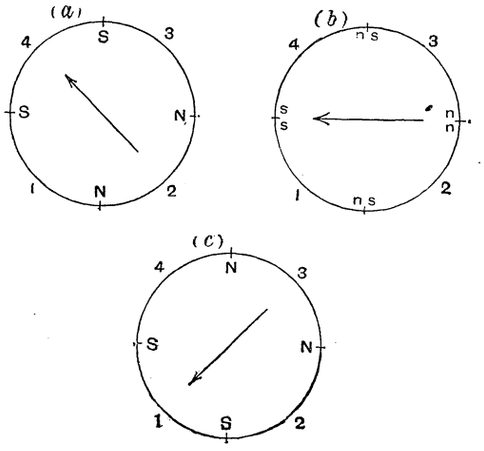

FIG. 5.—Magnetic State of a Rotary Field, at times differing by an eighth of a Period.

of this circuit is small compared with its resistance. The current that flows through the choking coil lags in phase nearly 90deg. behind the phase of the applied E.M.F. Hence (Fig. 4) the phase of the currents in (2) and (4) lags nearly 90deg. behind the phase of the currents in (1) and (3). When the currents in (1) and (3) have their maximum value the currents in (2) and (4) are nearly zero. The magnetic state that these currents tend to induce in the ring at this moment is shown in Fig. 5 (*a*), the arrow head denoting the direction of the lines of force. An eighth of a period later the magnetic state of the ring is as in (*b*), and after a quarter period as in (*c*). Hence the field is rotating in the direction 1, 2, 3, 4. It is an instructive exercise to draw diagrams as in Fig. 5, to show the direction of rotation when B and C (Fig. 4) are inter-

Hosted by Google

changed. In constructing a motor on this principle, the great object to be aimed at is to reduce the magnetic resistance of the air gap as much as possible. This has been very effectively done in the motors invented by Mr. C. E. L. Brown, and described in *The Electrician*, Jan. 27, 1893.

If we have n mains, the potential of each main differing in phase from the potential of the main next it by $360/n$deg., and if the final point of each main is joined to the final point of each neighbouring main by means of n equal intermediate wires which are wound consecutively round a soft iron ring, then, from symmetry, the currents in the intermediate wires would differ in phase by $360/n$deg. That is, all the currents in the wires would take their maximum values one after another, and a rotary field would be produced. It is to be noted that by winding a coil left-handedly instead of right-handedly the phase of its magnetising force is reversed. Hence four phases were got from the two-phased currents in Fig. 4.

It is not difficult, by splitting an alternating current into branch circuits which have different inductances, to produce currents which differ from one another in phase by $180/n$deg., then by winding the wires left-handedly and right-handedly on the ring to produce the same field as with polyphase currents. The method of measuring the power supplied by polyphase currents leads to some very pretty theorems in trigonometry, but at present they are likely to remain nothing more. The only real point of superiority of polyphase currents over alternating currents was in the ease with which they could be applied to work motors.

PHYSICAL SOCIETY.

At an ordinary meeting of this Society on March 24, 1893, Prof. A. W. Rücker, F.R.S., President, in the chair, several excellent photographs of flying bullets, and of the air waves produced by vibrating hammers, were exhibited, the originals of which had been taken by Prof. Mach. A Paper on

"The Differential Equation of Electric Flow,"

was read by Mr. T. H. Blakesley, M.A. The object of the Paper is to show that the ordinary mathematical expressions for electric flow fail to explain all known facts, and to point out that in order to interpret these facts, certain properties of matter not usually recognised must be admitted. The subject is treated both algebraically and geometrically in the latter case, the magnitudes being represented by the projections of the sides of a triangle revolving in its own plane on a fixed line in that plane. Taking the ordinary differential equation for a simple circuit having resistance and self-induction, viz., $V - L\,dc/dt = R\,C$, it is shown that this takes no account of any energy except that spent in heating the conductor, and that where radiation into space is concerned, it is necessary to introduce another term λC, where λ is a quantity of the nature of resistance. It is further pointed out that if work be done outside the circuit, the line which geometrically represents the induced E.M.F. cannot be perpendicular to that indicating the current and "effective" E.M.F., the latter term being defined to mean the value of the quantity which is numerically equal to the product of the current into the resistance. A magnetic phase-lag must, therefore, exist. The author also shows that a magnetic field induced in phase with the magnetic induction, would not result in a loss of energy and no hysteresis could exist. Under the same circumstances there could be no radiation of energy from an alternating magnet.

A Leyden jar, discharging through a circuit having self-induction is next considered. Taking the ordinary premises, it is shown that no provision is there made for energy radiated into space, and that magnetic lag is necessary for the existence of such phenomena. The differential equations for the variables in condenser discharges, according to ordinary assumptions, are shown to be of the same forms, and the variables can be represented by the projection of the sides of a triangle which is simultaneously undergoing uniform rotation and linear logarithmic shrinking. The rate of shrinking is the same as that of the radius vector of an equiangular spiral of characteristic angle β, where $\cos\beta = \sqrt{K/L} = R/2$; K, L, and R representing capacity, self-induction, and resistance respectively. The equations and their consequences are considered at some length, and several important properties brought out. To allow for radiated energy, R must be virtually increased from R to $R+\lambda$, and the total energy is divided between the circuit and the field in the ratio of R to λ. If, therefore, the circumstances be such that λ is large compared with R, say by having high frequency, the heating of the circuit may only be a small part of the total energy. In this direction the author thinks the true explanation of some of Tesla's experiments is to be found, the energy being expended chiefly in radiation and not in current through the experimenter's body. When obtaining photographs of rapidly-moving objects, Prof. Boys had used discharges of high frequency, but since several sparks of nearly equal intensity were obtained, the decay of amplitude was not very rapid, and the angle β of the logarithmic spiral representing the magnitudes would be nearly 90deg. For the most rapid discharge $\beta = 45°$, and the ratio of successive maxima was $e^{\pi}:1$, *i.e.*, 23·14 to 1.

DISCUSSION.

Prof. PERRY thought the C^2R term would not represent the heating of the wire when the oscillations were rapid, owing to the distribution of current not being uniform over the section of the conductor. Maxwell had shown that certain throttling terms had to be considered. In condenser discharges the complete equation would have many terms.

Prof. O. J. LODGE said the best definition of R in such cases was that derived from Joule's law rather than that of Ohm. Frequency was very important in the radiation of energy, but even at ordinary frequencies of alternators some energy was radiated. Referring to Tesla's experiments, he said the reason why no serious consequences followed was that there was not much energy behind them. High frequency might be instrumental in preventing injury, but this he thought remained to be proved.

Dr. SUMPNER pointed out that losses other than C^2R (R being the ordinary resistance of the conductor) had to be taken into account. In some cases, such as transformers on open circuit, the effective resistance might be 1,000 times that of the coil. To discuss completely the problem taken up by Mr. Blakesley, it would be necessary to take account of non-uniform distribution of current, both across and along the conductor, as well as the character of the magnetic and electric fields surrounding the circuit.

Mr. SWINBURNE thought there was a tendency to overestimate the rate of high-frequency currents, for unless the coils of transformers were assumed geometrically coincident, calculations were difficult. Errors of hundreds per cent. were quite possible. In Tesla's experiments no great power was involved, for the transformer could not give out any large power.

Mr. BLAKESLEY, in reply, said the term R was such that C^2R represented the whole waste loss in the conductor, whilst λ included everything wasted outside the conductor.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, April 7th.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Smoking Concert at St. James's Hall Restaurant.

MONDAY, April 10th.

SOCIETY OF ENGINEERS.

7:30 p.m. Ordinary Meeting. Paper to be read on "The Cleaning of Tramway and other Rails," by H. Conradi.

TUESDAY, April 11th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read with a view to discussion: "Steam-Engine Trials," by the late P. W. Willans, M.Inst.C.E. At this meeting the monthly ballot for members will be taken.

WEDNESDAY, April 12th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "The Construction of Locks and Safes," by Harry W. Chubb.

THURSDAY, April 13th.

ROYAL INSTITUTION.

3 p.m. Afternoon Discourse: "The Atmosphere," by Prof. Dewar, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Paper to be read: "Distribution of Power by Alternate-Current Motors," by Albion T. Snell, M. Inst. E.E.

FRIDAY, April 14th.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. Paper to be read: "The Manufacture and Efficiency of Armour-Plates," by D. Carnegie, Stud.Inst.C.E.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Seals," by Sir W. H. Flower F.R.S.

SATURDAY, April 15th.

ROYAL INSTITUTION.

3 p.m. Tyndall Lecture: "Some Applications of Electricity to Chemistry," by James Swinburne, M.Inst.E.E.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Hosted by Google

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.

[Editorial, Publishing, and Printing Offices :

SALISBURY COURT, FLEET ST., LONDON, E.C.

Telephone No. 2714. *Telegrams :* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street. London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.* "THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates —The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d
For the United Kingdom	5 0 ...	10 0 ...	19 6
For Foreign Parts and Colonies :—			
Within Postal Union	6 6 ...	12 6 ...	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Phillippine Islands, Siam, Transvaal, and Zanzibar	7 6 ...	14 6 ...	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" SERIES *at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.

The same in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. [*Nearly ready.*

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. [*Nearly ready.*

DRUM ARMATURE WINDING, AND COMMUTATORS: In Theory and Practice. By F. M. WEYMOUTH. [*Nearly ready.*

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRICITY AS A MOTIVE POWER. By A. T. SNELL. [*In preparation.*

Now Ready, in Two Volumes. Prospectuses Free.

THE ELECTRICIAN" PRIMERS. *Fully Illustrated.*

Price : Stout paper covers, 2s., post free, 2s. 2d. each ; strong cloth, 2s. 6d., post ree, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

EVAPORATIVE OR AIR CONDENSERS FOR STEAM-ENGINES.

Coal consumption is in one sense a comparatively unimportant item in the expenses of an electric-supply company, since it is only about one-fifth of the whole instead of about three-fifths, as in the case of isolated plants ; and it is for the most part proportional to the output. Salaries and other expenses of management, and the interest on plant, run on whether the load be heavy or light. Expensive plant for securing high economy is a burden to the capital account already loaded with copper mains and buildings. One of the accessories to the generating machinery which is often shirked by designers of supply stations is the condensing apparatus. Where there is a scanty supply of water it has been proposed in some cases to sink a well and to put down a pump ; but it may be objected, on the other hand, that nearly as much coal will be spent in pumping as will be saved by the vacuum. Some engineers, indeed, maintain that the friction of, and work done by, the air-pump is a serious proportion of the work gained. Again, when water is to be obtained, there is a difficulty about disposing of it, especially in stations hemmed in by streets. The cooling pond is a familiar adjunct to a factory in a manufacturing district, and it is not generally known that the Trafalgar-square fountains are the cooling ponds of the Government Waterworks at the back of the National Gallery. As fountains they have been derided, but if electric lighting is to be thoroughly municipalised the ingenious expedient may be repeated elsewhere, and more or less ornamental fountains may become common features in our squares and public places.

The chimney of the St. Pancras station carries a series of iron roof-like structures, roofing in nothing in particular and serving, in fact, as cooling screens over which the heated condensing water trickles. Somewhat analogous to this, but in principle to be preferred, is the air condenser or evaporative condenser, which is recommended often enough but seldom seen. SIR FREDERICK BRAMWELL and Mr. E. A. COWPER are well-known advocates of such a condenser, and we are glad to find some details of the apparatus in last week's *Industries*, in an article by Mr. MICHAEL LONGRIDGE. The condenser consists merely of a stack of pipes, through

Hosted by Google

which the exhaust steam passes, and over which the cooling water is allowed to trickle. They may be arranged in any convenient manner; the example described and illustrated in our contemporary consists of two horizontal cast iron pipes, into which are fitted a number of pairs of vertical pipes. A trough above the pipes distributes the cooling water, and part being evaporated, the rest falls into a tank and is pumped back again to the trough. A horizontal arrangement of pipes, on the other hand, would allow the principle of cooling to be used which is largely adopted in brewing and refrigerating plant. Here the fluid to be cooled ascends zigzaging up the stack of pipes, while the water trickles down; the result is that there is a fairly uniform difference in temperature between the interior and the exterior of the pipe at any part, and the work goes on more regularly. The principle is not quite so important in the case of steam, and whatever arrangement be adopted, the pipes must be sufficiently large to avoid any back pressure.

Mr. Longridge points out that, while the cooling surface of condensers in steamships is about one square foot per indicated horse-power, and for land engines in the tropics about two and a-half square feet, a much larger allowance, up to even ten square feet per indicated horse-power, is necessary for evaporative condensers. In surface condensers a large quantity of cooling water is used, and Mr. Longridge gives as an example a rise of temperature from 60° to 110°, each pound of water taking up fifty thermal units. The weight of the cooling water will be about twenty times the weight of the feed. With the evaporative condenser, on the other hand, while the surface over which it passes is greatly increased, the quantity is reduced until it becomes equal to, or even less in quantity than, the feed. Advocates of evaporative condensers assert, indeed, that not only is shortness of water no excuse for not condensing, but that such condensers will actually save water. The water cools the steam, not only by becoming warm, as in a surface condenser, but by turning into vapour; the air also becoming laden with vapour assists in carrying away a good deal of heat. Mr. Longridge gives the result of a test made with an evaporative condenser, in which a circulation of water was kept up and maintained by a supplementary supply of cold water from the town mains. A more complete test over a prolonged period would be of interest.

One drawback to this excellent system is the "washing day" effect of clouds of steam which are necessarily given off freely into the air. It is one thing to discharge exhaust steam up a properly constructed shaft at a considerable height above the neighbouring houses, and another thing to generate it on the roof of the station. Mr. Crompton has, we believe, contemplated housing an evaporative condenser under a roof, and allowing the steam to escape out of something of the nature of a shaft. But free access of cool air is essential to the efficient working of a condenser of this kind, and any check to its operation simply means an increase in the prime cost, since a larger condenser would be needed to do the work. The nuisance, however, would probably be more apparent than real, and the shades of night must necessarily fall before the time of full load comes on, and what would then be out of sight would probably be out of mind. But it is by no means necessary to provide a condensing plant capable of dealing with the exhaust of full-load working. It was pointed out by Mr. Willans that such condensers might with great advantage be employed on light loads. The construction of an evaporative condenser is extremely simple, and its use is burdened with no patents. No change need be made in the existing plant or in its working, unless, indeed, the lavish lubrication of the cylinders which is to be seen in some stations might interfere with the continuous circulation of the feed water.

PARALLEL DISTRIBUTION.

BY FRANCIS JEHL.

In the parallel system of distributing electricity, there are several methods that have been suggested, and which can be classified as follows:—Firstly, the direct system (Fig. 1); secondly, the feeder system (Fig. 2); thirdly, the loop system (Fig. 3); and fourthly, the double-loop system (Fig. 4). In the direct system the current is supplied directly to the points of consumption, and if we assume that the current density is the same throughout the metal used per square centimetre, and that the current is supplied at an equal rate per unit of length, we see that in the direct system the mains gradually taper off. In the feeder system we see that the principal mains or feeders must have the same cross-section throughout,

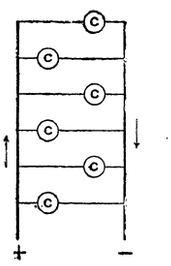

Fig. 1.

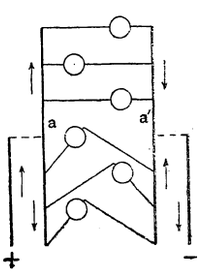

Fig. 2.

and that the secondary mains can be tapered off from the points at which they are fed a, a' in Fig. 2. In the single-loop system we have one main, a, Fig. 3, which gradually tapers off as in the direct system in Fig. 1, while the main, a', is of constant cross-section up to the point, b, and then tapers off downward. In the double-loop system, we have both mains, a, a', gradually tapering off, but at a lesser rate per unit of length than in the other systems. The above-mentioned systems form the elements of parallel distribution, and, of course, permit of further modifications, as per example, by taking two such systems as shown in Fig. 1. and connecting them in series and, using only one main in the centre, we have the principle of the Edison-Hopkinson three wire system, and which is extensively used in conjunction with the feeder system, also due to Edison. Now the principal

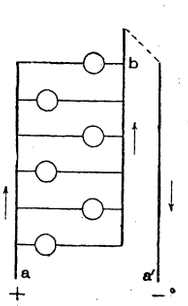

Fig. 3.

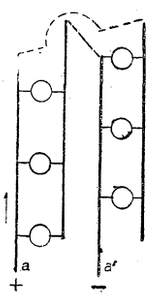

Fig. 4.

object to attain in the distributing of electrical energy is: (1) Economy, which is given by Lord Kelvin's law. (2) Safety, that is, having the necessary cross-section to prevent excessive heating. (3) Regulation, that is, to prevent too great a variation of potential along the leads. Let us now examine the four elementary systems shown above, and determine approximately the relative weight of metal used in each of them, assuming as before, a constant current density per square unit, and that the current is taken off equally per unit of length. The question of metal forms one of the principal items of the capital required in the distribution of electricity from central stations, and is therefore an important question to consider, in deciding upon which system we shall take. It is also clear that if the current density is the same throughout per square unit, the system having the most metal, will not only require a larger capital, but the yearly interest and redemption upon the same will be larger; and, also, the yearly costs of power wasted in the

Hosted by Google

mains will also be greater than in another system having less metal. Now in Fig. 1 we have six equidistant points, from which branches issue, and each branch consuming a constant quantity of current c. Taking the scale shown in the figure as reference to units of length, we see that up to the first unit of length, the main must have the necessary metal to carry six times the quantity of current c, and if we denote p as the necessary weight of metal to carry a unit of current per unit of length, we must have an amount of metal equal to $6\,p\,c$, for the second unit of length our amount would be $5\,p\,c$, for the third it would be $4\,p\,c$, and so on. Writing these amounts in a series, we get

$$6\,p\,c+5\,p\,c+4\,p\,c+3\,p\,c+2\,p\,c+p\,c$$
$$=p\,c\,[1+2+3+4+5+6]=21\,p\,c.$$

Thus $21\,cp$ is the amount of metal required for one main, in which the current density is constant. Double this amount, that is $42\,c\,p$ is the amount required for the system under consideration. This shows, that in the direct system, if the current decreases regularly per unit of length, and the density is to be constant, the quantity of metal required for the mains, is an amount which can be expressed by the sum of an arithmetical progression. Similarly we can calculate the weight of metal required for the other systems, noting from unit length to unit length the current in that part, and, multiplied by $p\,c$, summing up the parts will give the required amounts.

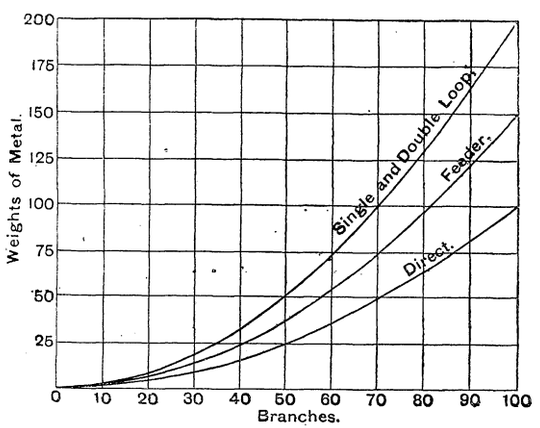

FIG. 5.

We will now give general formulæ to calculate the weight in any of the four elementary systems, assuming as before stated, that the quantity of current decreases regularly per unit of length. Let n denote the number of branches each taking c amount of current, and p the weight of metal per unit current and length. Let W equal the total weight of metal. We have then for the direct system

$$W_d=n\,(n+1)\,p\,c \quad . \quad . \quad . \quad . \quad . \quad (a),$$

for the feeder system,

$$W_f=[n\,(n/2+1)+n^2]\,p\,c \quad . \quad . \quad . \quad . \quad (b),$$

for the single-loop system,

$$W_l=(n\,(n+1)+n^2)\,p\,c \quad . \quad . \quad . \quad . \quad (c),$$

and for the double-loop system,

$$W_m=(2n\,(n+1)-n)\,p\,c \quad . \quad . \quad . \quad . \quad (d).$$

A further assumption is embedded in the above formulæ, b, c and d, and that is, that the relative lengths of the four systems is as 2 for the direct, 3 for the feeder and loop, and 4 for the double loop. The feeder always supplies the current in the middle, so that the total length of both is always equal to n units of length. Also in the loop system the one main carrying the whole current to b is equal to n unit of length.

In order to have a fair comparison between the four systems, n must be an even number and greater than two. Putting $n=$ successively 4, 6, 8, 10 we obtain the following figures, supposing c and p are each equal to unity. These figures show that the direct system is the one requiring the least amount of metal, and, therefore, absorbing the least amount of energy in the mains. From the formulæ a, b, c, and d we can construct curves, showing the *relative weight* of metal used in each system with a given number of branches, as shown in Fig. 5. The curves also show how the *relative difference* of weight between the different systems vary, as the number of branches increase, &c.

n =	Direct system.	Feeder system.	Single-loop system.	Double-loop system.
4	20	28	36	36
6	42	60	78	78
8	72	104	136	136
10	110	160	210	210

There is, however, another consideration to be noticed, and that is the question of regulation. It is now necessary to find which of the four systems will have the least variation of pressure between the first and last point of consumption. Theoretically, it is impossible to maintain a constant difference of potential between the various points, yet practice has shown us what limits are allowable, and which system admits of the best regulation, when the load varies from point to point. It was once claimed that in the loop systems, the pressure is always equalized, but this, will be shown later on, is not true. It is reasonable to suppose that whatever holds for an element of a system, will generally hold for the entire system. Now, in order to facilitate our calculations regarding the difference of pressure along the mains, we will assume that we have a given quantity of metal, from which our mains are to be made: further, that they are of constant cross-section, and therefore equal resistance per unit of length for each system. The direct system will evidently have the largest cross-section, while the double loop system the least. Let L_d equal the total length of the direct system's mains, S_d, the cross-section and δ the density of the metal employed. Then we have as the weight, W, of the whole mains $W=L_dS_d\delta$ (1) and by similar notations for the other systems.

$$W=L_fS_f\delta \ . \ . \ (2) \qquad =L_lS_l\delta \ . \ . \ (3) \qquad =L_mS_m\delta \ . \ . \ (4)$$

where L_f, L_l, L_m and S_f, S_l, S_m denote the lengths and cross-sections respectively of the feeder, loop, and double loop systems. These equations show that the ratio of their cross-sections are equal to the universe ratio of their length. Now the resistance of the direct system mains considered in one continuous length is $R_d=(L_d\,\rho)/S_d$ where ρ is the specific resistance of the metal. We have by substituting this value of S_d, namely $(L_d\,\rho)/R_d$, in the equation (1) and similarly for (2), (3) and (4) the following the following equations, each expressing the given amount of metal, W, used in our assumption

$$W=(L^2{}_d\,\delta\,\rho)/R_d \ . \ . \ (5) \qquad =(L^2{}_f\,\delta\,\rho)/R_f \ . \ . \ (6)$$
$$=(L^2{}_l\,\delta\,\rho)/R_l \ . \ . \ (7) \qquad =(L^2{}_m\,\delta\,\rho)/R_m \ . \ (8)$$

We may also suppose that the relative lengths of the conductors of the four elementary systems (each considered in one direct length) are $L_d=2$, $L_f=3$, $L_l=3$ and $L_m=4$. The assumption for L_d, L_l and L_m is correct, but in the case of the feeder, L_f, we have taken an average value. These values substituted in (5), (6), (7), and (8) give us

$$W=(4\,\delta\,\rho)/R_d \ . \ . \ (9) \qquad =(9\,\delta\,\rho)/R_f \ . \ . \ (10)$$
$$=(9\,\delta\,\rho/)R_l \ . \ . \ (11) \qquad =(16\,\delta\,\rho)/R_m \ . \ (12)$$

Now in Fig. 1 it can be easily verified, that, by calculating the fall of pressure from point to point along the mains, the loss in volts between the first and last parallel is

$$E_d=\frac{C}{2}\,(R_d) \quad . \quad . \quad . \quad . \quad . \quad . \quad (13)$$

C is the total current, and R_d as before the resistance of the leads. Of course, it is assumed that the current is taken off equally per unit of length. In the feeder system it is evident that the greatest difference is between the point of supply and the end parallels, and that we get

$$E_f=\tfrac{1}{2}\cdot\frac{C}{2}\cdot\tfrac{2}{3}\,R_f\,\tfrac{1}{2}=\frac{CR_f}{12} \quad . \quad . \quad . \quad . \quad (14)$$

Hosted by Google

It must here be noticed that the whole current C divides itself into two paths, as shown by the arrows in Fig. 2, and that we must therefore only take $\frac{1}{2}$ of C/2. The resistance R_f is that of the whole main feeders and secondary considered as one direct length, and as $\frac{2}{3}$ of this resistance is in the secondary, which at the same time is taken in multiple arc, we must take $\frac{1}{2}$ of $\frac{2}{3}$ in our formula. Now, taking the value of R_f from equations (9) and (10), we get $R_f = \frac{9}{4}.R_d$ and substituting this value in (14) we get

$$E_f = \frac{CR_f}{12} = \frac{C}{12}\frac{9}{4}R_d = \frac{3}{16}CR \quad . \quad . \quad . \quad (15)$$

Comparing equations 13 and 15 we see what an advantage is derived from the feeder system over the direct system. We have the same weight of metal in both systems, but in one we have about 2·6 times better regulation, that is, less variation of pressure.

(To be continued.)

THE INSULATION RESISTANCE OF PRIVATE-HOUSE CIRCUITS.

BY E. TREMLETT CARTER.

There seems to be some considerable diversity of opinion among the "authorities" as to what should be the standard of insulation resistance of a private-house lamp circuit. As a matter of fact, this diversity is really not confined to this particular case; for there is much difference of opinion regarding the insulation of street mains and of dynamos. But attention has been the more emphatically directed to private-house circuits by the number of carefully drawn up "rules" for the guidance of the contractor, and by the hopelessness of the task of trying to reconcile them. In the majority of cases these rules follow the logarithmic law, and it is natural and simple that they should do so; but it is not so much in the law of their variation as in the coefficients used that any reflection on their value is cast by their conflicting character. The single exception which we have been able to find to the hyperbolic law is that of the London Electric Supply Corporation Rule, which specifies an insulation resistance which is constant between definite limits, and which falls considerably as each limit is passed. But as this stepped system has a logarithmic decrement in the rate of fall from each successive step to the next, the rule is but an approximate hyperbolic law. All the rules, then, more or less closely follow the law which may be expressed thus: $r = k/n^2$; or, $R = k/n$, where r is the insulation resistance per lamp, and R is the insulation resistance for all the lamps, k being being the constant of resistance, or the number of megohms which the circuit should have if only one lamp were on the circuit.

Now it is in the numerical value of this constant, k, that the difference lies; and the extent of the diversity can be seen, either by a glance at the following table or by comparison of the curves given in the accompanying figure.

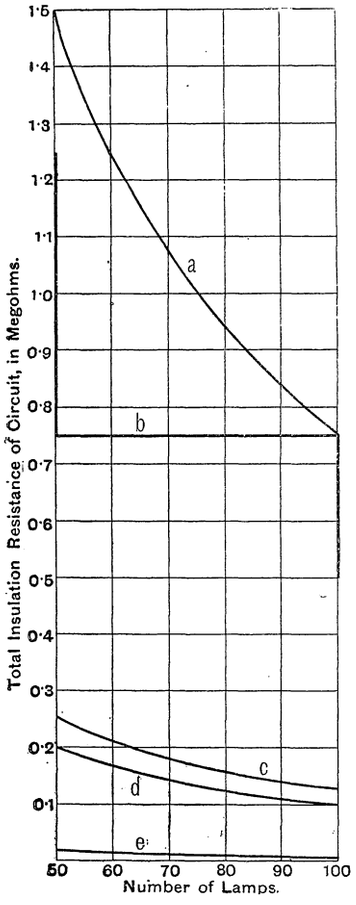
Authority.	Value of k.
London Electric Supply Corporation (maximum) ...	75 megohms,
" " " (minimum) ...	2 "
Phœnix Fire Office	12·5 "
Bradford Corporation	10·0 "
Prof. Jamieson	10·0 "
Institution of Electrical Engineers	0·87 "
Kempe	75 "

Turning to the curves, that marked *a* shows the values according to Kempe; the stepped values, constant between 50 and 100 lamps, are shown by *b*; *c* shows the Phœnix Fire Office rule; *d* the rules of the Bradford Corporation and of Prof. Jamieson; while the diminutive curve, *e*, represents the modest requirements of the Institution of Electrical Engineers in this matter. The stepped curve of the London Electric Corporation is better explained by the following details:—

From	1	to	25	lamps	R = 2
"	26	"	50	"	1·25
"	51	"	100	"	0·75
"	101	"	150	"	0·50

From which table it will be seen that this company demands a higher standard of insulation for large circuits than for small ones.

It might be thought that these diverse rules are the cause of the great difference which lies between the zenith and the nadir of almost every list of tenders in electric lighting work. Why is it that Messrs. A. and Co. can supply for £19,865 4s. 1¼d. what the highly respectable firm of Messrs. B. and Sons cannot undertake for less than the round sum of £50,000? Is it that the constant, k, of the former firm is only 0·87, while that of the latter is 75? But on looking into the matter, this solution proves of no avail; for one sees that a very wide range in actual insulation resistance is productive of only a trifling variation in the cost of materials.



Curve *a*, Kempe; *b*, London Electric Supply Corporation; *c*, Phœnix Fire Office; *d*, Bradford Corporation, and Prof. Jamieson; *e*, Institution of Electrical Engineers.

To wire a house with 1,000 megohms per mile does not cost three times the cost of wiring it with 300 megohms, even when the cost of wire alone is considered; while it does not cost 10 per cent. more when the percentage is taken on the total cost. This point has been recently brought out very fully by Prof. Ayrton, who shows that the actual cost of the best quality insulation is negligibly different from that of rubbish. The reason why the rubbish is used is not so much that it is cheaper in itself as that, where cheap and nasty work is done, there is absolutely no advantage to be gained by using good material; while the rubbish is a trifle easier to handle, and the work can be got over faster. The highly-respectable firms tender high prices, not because it costs them so much more to put in good material, but because they have a monopoly of first-class workmanship and can command their price.

Royal Institution.—On Saturday, April 15th, Mr. James Swinburne will begin a course of three lectures on "Some Applications of Electricity to Chemistry."

Hosted by Google

CONCENTRIC WIRING.

BY SYDNEY F. WALKER.

With much that Mr. Sam Mavor states in his article of February 17, 1893, the present writer fully agrees. Porcelain, though very pretty and a good insulator, is a very troublesome material to work with. Grooved boarding also, though excellent for the purpose for which it was originally designed, viz., to protect the insulation of the cables from mechanical injury, has the objectionable feature that its pores hold water, which will undoubtedly destroy the insulation, or at any rate will assist to. Further, connections to branches are not easily made in grooved boarding without, on the double-wire system, bringing the two joints dangerously near together, and sometimes straining the insulation of both main and branch cables. And these failings are not the sum total of the offences of the double-wire system with grooved boarding. But while on the one hand it is very doubtful whether concentric wiring will cure the ills referred to, on the other hand it is quite certain that the whole of them can be very much reduced, if not entirely got rid of, by care and thought both in designing and in constructing. Electrical engineers are far too apt to follow one another like sheep do their bell wether. Now they all declare that one form or one type of apparatus is, *par excellence*, the best that could possibly be designed, and a short while hence they are equally as enthusiastic over some totally different type, presenting just the opposite qualities. In neither case have they taken much trouble to examine for themselves whether the apparatus is really adapted for the work it will be called upon to do, and whether it can stand the trials to which it will be subject.

This or that eminent man has declared for the apparatus, possibly under very different conditions to those in which it is now intended to be used, and that is sufficient. For instance, if it be acknowledged that grooved boarding is good, provided it harmonises with the decorations in private houses and does not hold water, would it not be worth inquiry whether it may not be possible to prevent its holding water? If the pores of the wood be filled with an insulating and waterproof substance, the boarding should not hold water so long as this is present. But here again care and thought, or their absence, will make all the difference between obtaining any advantage from this and the reverse. Filling the pores of the wood with shellac, for instance, or with any substance that is an insulator and that will withstand moisture and the other conditions that may be present, gets rid of the difficulty at once; but the pores should be filled, the wood being thoroughly dried first and before the wires are laid in the grooves, not merely a coat or two given afterwards without any thought as to whether moisture may not be already present. Shellac, too, may not be the best substance to use under all conditions.

It will be considered a truism to say that care in making the joints and in placing them will reduce the troubles Mr. Mavor refers to, yet it is well known that careless jointing is at the bottom of a great many of those troubles, and would be equally present with concentric wiring.

But, now, as to concentric wiring as the panacea. The writer's first objection to this is that it infringes a rule which he believes to be necessary for the duration of cables used for electric lighting, viz., that there shall be no metallic conductor outside the insulating envelope. He believes, and his experience has borne out his belief, that the act of putting on the outer conductor necessarily strains and often damages the insulating envelope. Though the fault is often not detected, even by very careful tests, it leads to the breakdown of the cable later on, and considerably shortens its life. The writer's second objection is the necessity advanced by Mr. Mavor of earthing the outer conductor. He most strongly objects to "earth," as it is called, being connected to any electric lighting system at all, and for the reason, among others, that when you have secured good "earth" you have introduced into your lighting system a mass of conductors over which you have no control, and in which, and to and from which, you will have currents passing over which you have also no control, and which will invariably lead to trouble. A little consideration will show that the idea that by connecting to "earth" you are making one conductor of absolute zero potential is a mistake. With alternating currents, for instance, how can either conductor be at zero when each in turn is positive and negative? And with direct currents there can be no zero of potential, though there may be two or more points at the same potential; but these points, from the very nature of the case, cannot be points in the same conductor.

It is, perhaps, hardly necessary to refer to the case of the troubles in connection with the St. James's Company's mains, though those troubles afford a striking illustration of the points the writer has been endeavouring to enforce. The known disturbance to ship's compasses, not only from the leads but from the return through the body of the ship, is also another striking illustration of the point. In fact, wherever you connect a source of electricity to a conductor, you communicate the electrical condition existing at the point of junction to that point only. The electrical condition of every other part of the conductor must differ from that at the point of junction. Mr. Mavor is also mistaken in supposing that a concentric cable cannot create a fire.

The writer has in his possession a piece of a cable, virtually a concentric cable, though the outer wires were of iron, which set fire to a cotton cargo by means of a spark which passed between the inner and outer conductors. One of the latter was fused. In this case Mr. Mavor's rule had been rigidly observed. The outer conductor was in contact with the body of the ship everywhere, and one side of the dynamo was connected directly to the ship. The writer's view of the question is that where damp is or may be present, it should be excluded from the insulation of the cable proper, and that in damp places the insulation should only be broken where it is absolutely necessary. He prefers to use double the length of cable or more, if by so doing he can avoid a joint where damp may be present.

Another rule of the writers's is, when you are obliged to make a connection in places where damp may penetrate, make the connection where and by such means as will enable it to be always in sight. Never hide your connections in damp places; make them as large as you possibly can, and repair the work the damp has accomplished as frequently as possible.

A SECONDARY STANDARD FOR ARC-LIGHT PHOTOMETRY.

At the meeting of the Société Internationale des Electriciens on March 1st, M. Blondel made some interesting suggestions with regard to a secondary standard for arc-light photometry. The following is a verbatim translation of M. Blondel's remarks as reported in the *Bulletin* of the Société Internationale:—

As to material standards the only one I wish to refer to is the photometric standard, for which as a secondary standard the American Institute of Electrical Engineers propose the Hefner-Alteneck amyl-acetate lamp, arranged so as to exactly reproduce the *bougie-décimale*. This proposal does not appear to me to be a very happy one. First of all, the unit definitely chosen by the Congress of 1889 being the Violle platinum standard, the secondary standard adopted in each country or in each laboratory for lights of the same tint is a matter of little importance provided it is sufficiently constant and that its value as a function of the unit is known and can be easily verified. There is an especial reason for not abandoning the *carcel* in France, where it has been used so long, since it is almost exactly half a *violle*. Complete freedom of action ought to be retained in this matter, and it should only be recommended to standardising laboratories to employ the Violle portable apparatus as arranged by its inventor. Secondly, all lamps or candles, and even the Violle standard, possess this serious and well-known defect, namely, that owing to the composition of their light, they do not lend themselves to a comparison with the light of arc lamps. Now the amyl-acetate standard is precisely the most red of any at present in use, and this fact must be added to those cited above to prevent its employment being prescribed. Arc-light

Hosted by Google

photometry is, in fact, the only class which can necessitate the choice of a special secondary standard. This matter is so important from this point of view that I ask permission to show you a little piece of apparatus which I have recently had made for this very purpose, and to refer briefly to the considerations which justify its adoption as a secondary standard.

At present it is extremely difficult to measure, even roughly, the photometric intensity of an arc lamp for the following reasons:—Everyone who has carried out arc-light measurements knows how hard it is to equalise the sensation produced by this light and by the standards of light now in use. The relative value of these sensations depends in a large measure upon the conformation of the eye of the observer and the dimensions and illumination of the areas under observation. Many people rest content with a very rough approximation. Others get out of the difficulty by interposing a red or green glass, or both successively, often without making clear the exact meaning of the results so obtained. Others again, to a small extent, have recourse to the photometry of differently-coloured lights, the learned flavour of the method concealing its frail and, at times, inaccurately-laid foundations. In any case there is complication, with its consequent doubtful results.

Even admitting that by some means or other two differently-coloured lights have been balanced for a given objective value of the illumination, the balance will be upset when the objective value is changed in virtue of the Purkinje phenomenon.

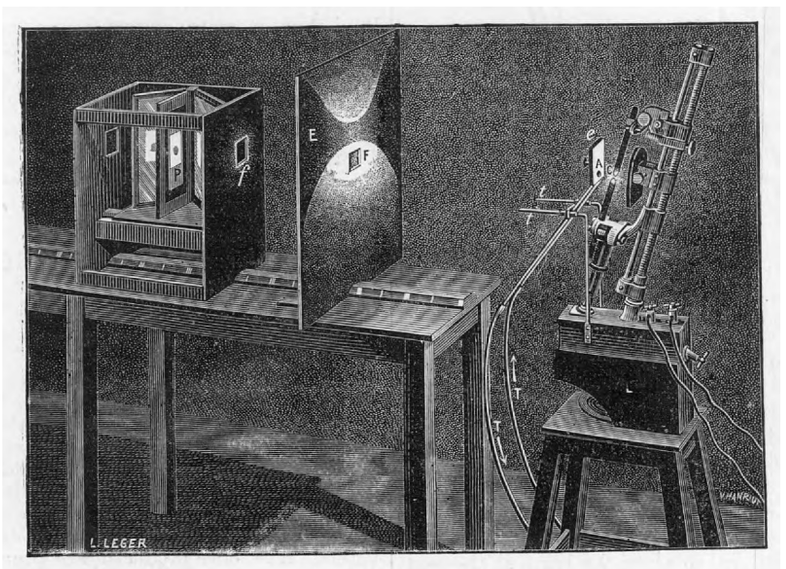


FIG. 1.—General View of Photometric Arrangement.

L, Sautter-Harlé lamp. C, positive crater. *e*, screen, cooled by a stream of water. *t t*, rods. T T, water-tubes. E, screen. F, aperture in screen. P, photometer. *f*, photometer slit.

Finally, if two illuminations are balanced by a comparison of two diffusing surfaces they will not be so from the point of view of visual perceptivity, that is to say, for reading purposes or clear distinction of detail.

It is, therefore, impossible to satisfactorily define the light of an arc lamp as a function of existing standards, and this can only be done by means of a standard of the same tint, having as its source the electric arc. The principle underlyi ngthe method I employ for this purpose, which is, as we shall see, the isolation on the positive crater of the arc of a given light-emitting surface, requires some preliminary explanation.

MM. Abney* and Violle have in turn demonstrated the constancy of the spectral composition of the light of the crater, and, consequently, the constancy of the temperature apart from the current strength. This constancy of the temperature had, indeed, already been proved by M. Rossetti, and Prof. Silvanus Thompson had discovered the cause* of it in the volatilisation of the carbon at the point of passage, a volatilisation which requires a constant expenditure of energy, and is carried out at a fixed temperature. But it has not been shown up to the present that the intrinsic brilliancy of the surface of the crater is independent of the density and the molecular structure of the carbons employed. In fact, it is not enough to get a constant temperature if we wish to have a constant brilliancy; the emissivity must be independent of the molecular structure, and, as we know, this condition is far from being fulfilled in incandescent lamps.

As experiment alone was capable of giving an answer on these points, in conjunction with M. Le Chatelier, and by the aid of the ingenious pyrometer devised by him, I carried out a series of determinations of the intrinsic brilliancy under the most varied conditions of voltage and current, and with carbons of very different nature and composition supplied by various firms, but chiefly by the Société Le Carbone, to whom I must express my thanks. The samples sent by this Company comprised the most widely different types—hard and soft, homogeneous, and without cores, for high and low voltages. Contrary to our expectations, all the values of the brilliancy obtained by us sensibly agreed; the deviations were always irregular and did not exceed the limits of experimental error, limits which are unfortunately somewhat wide in pyrophotometry. For the degree of accuracy which we were able to attain it may be concluded that provided the carbon used is sufficiently pure—that is to say, with the exception of the core, free from mineral substances likely to lower its point of volatilisation—the intrinsic brilliancy of the zone of maximum brilliancy in the positive crater is practically constant, and is not only independent of the current but also of the molecular state and density of the carbons used.†

Such being the case, the crater possesses the principal properties necessary for a standard of light, upon the sole condition that we isolate a given emitting surface in the zone of maximum brilliancy. Moreover, thanks to the fact that incandescent carbon follows Lambert's law of emission, it is not necessary that emission should occur normally to the incandescent surface.

I have devised, I think the first, an apparatus fulfilling the requirements of a practical standard, and capable of being

* In a letter which he was good enough to send me on this matter, Prof. Silvanus Thompson informs me that Captain Abney in a report to the English Secretary of State for War showed a few years ago, for the first time, the constancy of the spectral composition of the light emitted by the positive crater and, moreover, employed, with a view of constructing a standard spectrum, a method analogous to that which I now make use of for obtaining a standard of light. Although the report referred to has never been published, and that, as far as I know, there has been no allusion to this subject in photometric treatises previous to this communication, I think it my duty to call attention to the priority of Captain Abney in this matter, remarking merely that my point of view is decidedly different, as is also the law which serves as my point of departure.

* "Arc Lamps and their Mechanisms." By Prof. S. P. Thompson. A Paper read before the Society of Arts, March 6, 1889.

† If more accurate experiments show that there are appreciable differences in the emissivity, the difficulty can be got over by always working with the same carbon after having standardised against a Violle standard.

Hosted by Google

manipulated with as much ease as an ordinary standard. This apparatus, which I have the honour to exhibit before the Society, comprises essentially a lamp with oblique carbons, a luminous point which can be regulated and a vertical screen with a variable diaphragm (Fig. 1).*

The lamp I employed is one which lends itself very readily to the purpose in hand; it was a projector lamp lent me by MM. Sautter et Harlé. The carbons are both inclined at an angle of about 20deg. to the vertical. Owing to this inclination, the positive crater on the upper carbon presents a surface which is inclined about 50deg. to 60deg. to the vertical, and it is easy to disengage it completely from the lower carbon by displacing the arc 4 to 5 mm.† The opaque screen (Fig. 2), formed by a little flat box bent in the middle, and continually cooled internally by a current of water‡ can be moved in a horizontal direction in front of the arc along two rods acting as sliders and fixed to the base of the lamp. The screen is pierced at the bend by a small conical hole, behind which revolves a disc provided with a number of apertures of known dimensions. An area of one square millimetre seems particularly appropriate to arc-lamp investigations, in which it is usually advantageous to employ a standard more powerful than ordinary standards. The aperture in the diaphragm is placed on a level with the centre of the crater and at

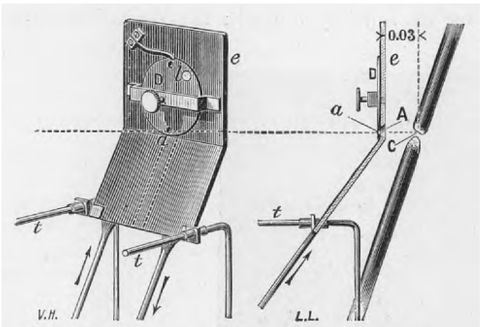

FIG. 2.—Details of the Apparatus. Perspective View and Vertical Section. D, pierced disc. A, conical aperture. *a*, square millimetre aperture. *l*, lens.

a very short distance (two to three centimetres) from it. In this way a conical and divergent beam of light is obtained, having as its centre the base of the crater and the small aperture; its horizontal intensity is equal to the intrinsic brilliancy of the corresponding portion of the crater multiplied by the area of the aperture employed.

The standard thus constructed and which we may call the *arc standard* is employed in the same way as any other photometric standard. It is sufficient to place the lamp at the end of a photometer bench and arrange the hole in the diaphragm at the same height as the centre of the photometer screen, which may be of any type, Bunsen, Foucault, Mascart, &c. The sole, but indispensable, condition to be fulfilled is that the horizontal rays impinging upon the photometer shall come well from that portion of the crater which has the maximum brilliancy, which is the only portion giving a constant light. With this view two precautions have to be taken.

(I.) A fairly large, regular, uniform crater must be obtained. This is arrived at by employing a sufficient voltage to ensure complete stability, that is to say, we must have at least 70 to 75 volts at the lamp terminals, including the rheostat, and in addition a current density of at least 0·2 ampere per square millimetre.§‖

(II.) It is necessary to make sure before each reading that the light received by the photometer really does come from the most brilliant part of the crater. This is easily done by bringing a little lens, the focal length of which has been chosen so that the crater is at its focus, behind the opening in the screen. A highly-magnified and sharply-defined image of the arc is then thrown on a vertical screen placed in front of or behind the photometer, and we can see in what part of the image the aperture is. The image of the positive carbon is projected in the shape of a very clear elliptical surface, the length of which may attain several metres, the upper edge standing out clearly on a black ground. When the lamp works well, this edge is almost the brightest, and it is within this portion of the image that the photometer aperture ought to be.* Adjustment is carried out very easily by placing the lamp in the proper direction and then raising the arc by means of the lever provided for that purpose. As soon as the adjustment is correct, an aperture of known size is brought into action, and the reading is taken.

The average illumination at the photometer is constant, but small rapid variations from the mean occur, which are due either to variations in the phenomenon of volatilisation or to the flame which rises up in front of the crater. This flame can be easily blown away and the arc concentrated more decidedly on the edge of the crater by suitably arranging a fairly powerful directing magnet. These variations do not allow us to make an absolute standard of this apparatus in the same sense as the Violle standard is absolute. But for measuring the candle-power of arc lamps, the light of which is of the same kind though more powerful, and which constantly undergoes, moreover, considerable variations from the average intensity, the use of the *arc-standard* cannot give rise to any objections on this score. I think, moreover, that I have shown that the manipulation and the adjustment are very simple.†

* We are indebted to *L'Industrie Electrique* for these *clichés*.—[Ed. *E.*]

† One could also employ, though it would be less convenient, a lamp with vertical carbons, and use an oblique screen, adding a mirror to reflect the ray horizontally. It would be necessary then to take into account the coefficient of reflection of the mirror.

‡ If water cooling is found somewhat of a nuisance, the metallic screen may be replaced by a similar one made of some refractory porcelain.

§ For instance, good results are obtained with 15mm. carbons, 75 volts, 40 amperes and a 5mm. arc, although 10mm. carbons (provided they are of good quality) and 25 amperes will do. If the arc is constantly moving the crater no longer remains uniformly brilliant, and either the conditions of supply or the type of carbons employed should be altered.

‖ 0·2 ampere per sq. mm. = 129 amperes per sq. in.—[Ed. *E.*]

ON THE KATHODE RAYS IN GASES AT THE PRESSURE OF THE ATMOSPHERE AND IN THE HIGHEST VACUUM.‡

BY DR. PHILIPP LENARD.

The rays producing phosphorescence, which are projected from the kathode of a Geissler tube, are, according to Hertz, transmitted by thin metal plates. If it were possible to find a metallic plate of a thickness sufficient to resist the external atmospheric pressure without losing its transparency, we should be able, by closing a hole in the discharge tube by this plate, to allow these rays to enter the air outside. This idea is realised in the experiments a short description of which I lay before the Academy. It is shown by these that the kathode rays, once produced, are propagated through a space filled with air; this fact offers greater facilities for their observation, and it is thus made possible to choose and vary the conditions of observation independently of those of production.

Apparatus.—The figure shows a section of a convenient form of the apparatus. E E is the glass discharge tube, K the kathode, an aluminium disc 12 mm. in diameter, A the anode, which is preferably made with a large surface. Opposite the kathode the tube is closed by a strong metal plate *m m*, perforated at F to a diameter of 1·7 mm. Over this perforation cemented from the outside is a plate of beaten aluminium 0·003mm. thick. This covering, which is transparent to kathode rays, but totally bars the passage of light and air, I call the window, and the space to the left of it, the observing space. The distance between the kathode and the window is 12cm.; the latter is shut off from the discharge by the screen V, and is thus protected from being acted on. On the outside, the large metal screen S S is attached to the window support, and to this the tin cover G G is fixed. The latter, as well as the screen S S, the anode, and the positive pole of a large induction coil, are conducted to earth, the negative pole being connected to the kathode. The arrangement chosen leaves the observing space almost perfectly free from light and the forces of the electric discharge. The best exhaustion in the discharge tube is reached when the difference of potential between the electrodes corresponds

* Cored carbons may be used upon the sole condition that the dark image of the core is not thrown on the photometer.

† These experiments were carried out at the Central Laboratory of the Société Internationale des Électriciens, which is always so hospitably opened to all investigations of the kind, with the assistance of MM. Guilbert and Guiard.

‡ Communicated to the Royal Prussian Academy of Sciences by Prof. von Helmholtz.

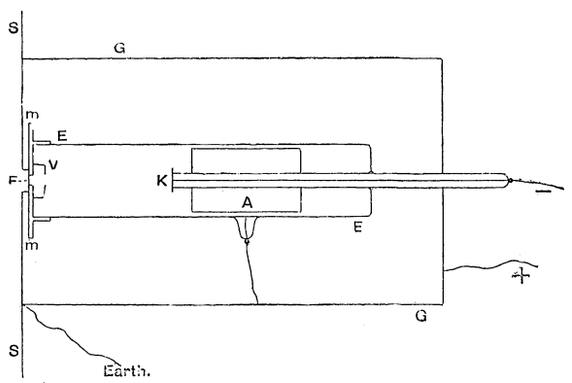
Hosted by Google

to a length of spark of 3cm. between tubes in air. As regards the phenomena seen in the observing space, I have been able to ascertain the following, besides some less important things.

Kathode Rays in the Open Air.

The kathode rays produce a slight luminosity in the air. A bluish light surrounds the window, which is somewhat bright at its surface only. A strong smell of ozone is noticed.

Phosphorescent bodies held near the window shine on the side turned towards it brightly with the light peculiar to them. With increase of distance from the window the phenomenon diminishes rapidly in intensity, disappearing at a distance of about 6cm. It is only the distance which determines the brightness of the luminosity. The direction is without influence, which is not surprising, since kathode rays pass diffusively through aluminium. Phosphides of the alkalies, common and uranium glass, calcspar, fluorspar, and other minerals, pentadecylparatolylketone and asaron, all glow with the same colour and relative brightness as they do in vacuum tubes within the range of the kathode rays. The luminosity is particularly great in the phosphides of the alkaline earths and the carbon compounds mentioned. Among liquids, a drop of petroleum showed its blue fluorescence. Metals, quartz, mica, and eosine-gelatine, which is strongly affected by light, remained non-luminous, as in vacuum tubes; also aqueous solutions of eosine and fluorescein, and the ether solution of chlorophyll. All phenomena of phosphorescence in the observing space cease as soon as a magnet attached to the discharge-tube prevents the kathode rays from reaching the inner surface of the window.



A quartz plate, 0·5mm. thick and not too small, introduced anywhere between the window and a phosporescent body, stops its luminosity. An ordinary gold, copper, or aluminium leaf leaves it almost undiminished. Whether, however, a substance is transparent or not depends entirely upon the thickness of the layer employed. I have not found a solid body perceptibly transparent with the thickness of a fifth of a millimetre or more, whereas thin layers of all bodies were partially transparent, such as stout writing paper, collodium films, aluminium foil up to 0·03mm. thick, thin blown glass, very thin split mica. Almost perfectly transparent are, besides the metal foils already mentioned, tissue paper and soap films showing colours below the sixth order.

The atmosphere is a turbid medium for kathode rays. They are not propagated in straight lines, but diffused. The phosphorescence effects penetrate into the shadow of an opaque body projected from the window, and it is not possible to cut off sharply defined rays 1cm. long by means of diaphragms. If a metal plate with a sharp-edged opening about 1mm. wide is placed in the way of the kathode rays, a sharp, bright image of the opening is only obtained immediately behind it. At the distance of 3mm. the image is already enlarged five times and diffused, and at 12mm. the screen is equally illuminated almost all over.

Kathode Rays in a Vacuum.

It is a fundamental question concerning the nature of kathode rays, whether their propagation is conditioned by the presence of matter, or whether they also pass through empty space. The impossibility of generating kathode rays in a perfect vacuum has up to the present stood in the way of an answer to this question. It is now possible to overcome this impediment. We produce the rays as before, but surround the observing space with glass walls and exhaust it. As the exhaustion proceeds, the distances within which phosphorescence phenomena are observed increases, and the rays cut off by a diaphragm are better defined. When the degree of exhaustion is reached at which the kathode rays are usually studied, the phosphorescence of the glass wall of the observing space, besides an increased intensity, indicates rectilinear propagation in all directions from the window. The length of the rays, pretty sharply defined, was carried to 30cm., and was only limited by the walls. From this degree of exhaustion up to extreme exhaustion there is little change. The rays only appear a little sharper, the glass phosphorescence somewhat brighter. With this extreme exhaustion, at which the mercury pump ceases to act—the most sensitive test for a gaseous residuum—the electric charge fails. It is no longer possible to produce a discharge between two aluminium plates fixed within the observing space. Discharge takes place along the outer surface of the glass, although the electrodes are 20cm. apart. We can hardly ascribe sensible effects to such imperceptible traces of matter. Granting this, our experiment proves that kathode rays are processes in the ether. If they were material processes the highly vacuous space ought to have been practically impenetrable to them. To these experiments may be added the fact that in the case of all degrees of exhaustion permitting something like a distinct formation of rays, a strong deflection of these rays by the magnet was observed.

Kathode Rays in Various Gases.

Different gases are turbid media to very different degrees; greater definition is accompanied by greater transparency. On letting coal gas escape between the window and the phosphorescent screen, a considerable increase of brightness is noticed on the screen. On filling the observing space with hydrogen at ordinary pressure enclosed in glass, the phosphorescence phenomena extend as far as 20cm. from the window, or more than three times as far as in air at equal pressure. It is also possible to cut off rays by means of a diaphragm which give pretty sharp patches up to a distance of 3cm. These rays in hydrogen at ordinary pressures are strongly deflected by the magnet. Oxygen is just perceptibly less transparent than air, and just about as turbid. Carbonic acid is much less transparent, all the phenomena in this gas being confined to distances up to 4cm. from the window. Rays, even of a few millimetres, cannot be obtained.

From these phenomena we may argue that very small dimensions affect the kathode rays. Even for light of the smallest known wave-length, matter behaves as if filling space continuously; here, on the contrary, the behaviour of elementary gases even is that of a non-homogeneous medium, each individual molecule acting as a separate impediment. The number of molecules upon which the kathode rays impinge in equal volumes of different gases is always the same; we may, therefore, say that hydrogen molecules render the ether much less turbid than oxygen molecules, and the latter less than carbonic acid molecules.

NOTES ON CERTAIN PROPOSALS FOR PATENT LAW REFORM.*

BY W. LLOYD WISE, FELLOW OF THE CHARTERED INSTITUTE OF PATENT AGENTS.

Amongst the matters that will be considered shortly by the Associated Chambers of Commerce are certain proposals for Patent Law reform. Hence, seeing that there is an agitation for alteration in the Patent Laws that, in various forms, have done so much to promote the advancement of the industrial arts in the United Kingdom, it becomes important to watch closely the suggestions put forward. This is the more necessary because many persons who dabble in matters of this kind are possessed (in regard to the matter in hand) of that most dangerous of things, a little knowledge.

Although the Government fees have recently been largely reduced, so that they now amount to only £99 for fourteen years, there is a widespread feeling in favour of further reduction, and it has been suggested that the fees for a fourteen years' patent should be brought down to £25. It seems reasonable to give the present scale a fair trial before rushing into a further reduction. But the principle appears sound, that as patentees are liable to the payment of income-tax like other persons, they should not be exceptionally taxed, in respect of their inventions, to an extent beyond that which is necessary to support the Patent Office and carry out its work on a thoroughly efficient basis.

Another suggestion is that patent applications should be officially examined, and when granted should be "absolute." Such a system appears to be utterly impracticable. At any rate, since, under the new German law, it is provided that proceedings for declaration of nullity shall not be allowable if instituted after the expiration of five years from the date on which the publication of the grant was effected, the least that can be judiciously done is to wait and see how that system is found to work, before attempting in this country such a dangerous experiment as is proposed.

* From the *Chamber of Commerce Journal.*

Hosted by Google

There is a wide-spread belief amongst Germans and others having special and extensive experience in patent matters, that the attempt to make patents indefeasible will prove a failure; because, on the one hand, it is impossible by any system of examination to make sure that an invention is absolutely new, even within the country for which the patent is demanded, and, on the other hand, it must be grossly unjust, and may prove disastrous, to deny to any one charged with infringement of a patent the right to show, in self-defence, that the patent in question ought never to have been granted. It is quite contrary to English ideas to arbitrarily take from any one any freedom he may have legitimately enjoyed, and this to enable others to enjoy a monopoly at the expense of their fellow-men.

The suggestion that patents, when granted, should be absolute surely cannot have been the result of mature consideration on the part of persons having large experience of patent matters in general, and of the practical working of preliminary examination systems in particular. Those who propose absolute patents also make another suggestion, a very superficial consideration of which will (if regard be had to the history of progress in the industrial arts, due to successive improvements) at once show how impolitic, not to say impracticable, such a scheme must be. There is a suggestion, that will be presently dealt with, to the effect that an impracticable or unworkable patent should not invalidate a later though similar workable patent. Here at once is implied an admission that no system of examination will suffice to prevent the granting of patents for impracticable and unworkable inventions. Could anything be more illogical than to grant an absolute patent for an impracticable or unworkable idea, thus entitling the grantee to levy blackmail from those who may subsequently produce a practicable and workable thing? The policy of the Patent Law is, and should be, to grant to those who devote themselves to the improvement and advancement of the manufacturing arts a reward, in the form of an exclusive privilege of limited duration, in return for the benefit conferred upon the community by the disclosure of some new and useful invention, which, on the expiration of the term of exclusive privilege, the public at large will be at liberty to freely exercise and enjoy. This consideration, and every other consideration, would be utterly wanting in the case of an exclusive privilege granted in respect of an impracticable or unworkable idea. But this is not all. The grave responsibility cast upon those charged with the administration of the law when determining whether or no Letters Patent should be granted in a given case, must inevitably result in a practice of granting patents very sparingly. The effect would unquestionably be to damp the progress of invention by refusal of patents for improvements which, from an examination of the mere specification, might appear unimportant, but which, if allowed to go forth as the subject matter of Letters Patent granted to the applicant at his own risk and without Government guarantee, and to be commercially introduced, might be productive of the most beneficial results. When it is remembered that in cases of litigation experts of eminence constantly differ, when on oath, as to whether two things are practically the same; as to whether one thing is an improvement on another; as to whether one thing will work and another will not, and so forth; and this after the invention forming the subject matter of the patent in dispute has been introduced into practical use, it is only natural to ask what conceivable kind of a staff of examiners could be entrusted with the investigation and decision, from documents alone, of questions of the exceedingly intricate and highly important nature necessarily involved in the determination of the question whether a given invention should or should not become absolutely and exclusively, for a term of years, the property of the person seeking that privilege.

An inventor who applies for a patent surely (as a rule) does so in the belief that his invention is new, that it is workable, and that it is valuable. He may be mistaken; sometimes the most experienced of men in a given profession or trade are mistaken. Sometimes an invention promising the most favourable result on paper, turns out, when put into practice, to be a failure, or at least to need very material modification before it will work. But if those with practical experience who have devoted special consideration to the matter are unable to perceive defects, how is it to be expected that examiners, dealing with innumerable cases involving a variety of subjects, could be relied upon to form a correct judgment? In the same connection, let it be remembered that inventions which men of experience have pronounced impracticable have sometimes proved not only practicable but exceedingly valuable. In such a case what is to compensate, not only the unfortunate inventor, but also the community, for the loss incidental to the improper refusal of a patent, and the consequent loss to the public of the benefits that would have accrued from the early introduction of the invention into the market?

And last, though not least, let it be remembered that the granting of absolute patents would render it necessary for every manufacturer to incur the anxiety and expense of at least continually employing some one (in some cases it might be quite a staff) to watch closely, and from time to time take steps that might by costly, with a view to preventing anyone getting a patent for something already used in the manufacturer's own works; because should a patent once issue, the manufacturer would be entirely at the mercy of the patentee, and might be compelled to leave off doing that which he might have been doing, even continuously and on a large scale, perhaps for years.

As an alternative, it has been suggested that it should be so arranged that Patent Office officials should carry out searches on behalf of inventors. If this means that every application for a patent should be subjected to examination as to novelty, it is quite possible that a workable system might be devised. But those who talk about the advantages of the examination systems that obtain in the United States and in Germany have yet a great deal to learn. They evidently have not any idea of the large proportion of invalid patents that are granted, notwithstanding the irritating investigations and the often unreasonable requirements of officials. They are ignorant as to the large number of patents which, after being granted, are declared invalid, both in Germany and the United States, and in the case of the United States, of whose patent system many of the uninitiated seem to be enamoured, they little dream of the enormous amount of money that is being constantly spent in litigation concerning the validity of such grants; nor do those who so urgently demand an exhaustive official examination preparatory to the grant of Letters Patent, know how often patents have been refused for meritorious inventions. We do not want in this country a system under which patents might be refused for inventions of such importance, for examples, as the Bessemer Process or the Siemens Regenerative Furnace. If the proposal under notice means that Patent Office officials should undertake to perform for inventors work now entrusted to patent agents, the way will be paved to an interesting inquiry. It will naturally be asked to what extent the principle is to be conceded of providing officials at the public expense to perform for the benefit of a class work which a number of tax-payers have specially qualified themselves to undertake, and whereby they obtain a livelihood. It is only necessary, for the moment, to add, that the attempt made under the Act of 1883 to enable inventors to dispense with professional aid has lamentably failed, as was to be expected. In a very large proportion of cases, notwithstanding the official examination, the patents taken out without professional assistance by persons ignorant of even the elementary principles of patent law and practice, have literally been worthless. Such provisions are simply misleading, and have the effect of frequently depriving the luckless inventor of the benefit he might otherwise have derived from his invention.

A further proposal is that a time limit may be fixed, beyond which an impracticable or unworkable patent should not invalidate a later though similar workable patent. It will be interesting to learn what is meant by this suggestion. If it has any meaning whatever, it rather seems to indicate that, contrary to precedent, up to a certain time an impracticable or unworkable patent *should* invalidate a later though similar workable patent. It is well recognised by our Courts that an antecedent specification ought not to be held to be an anticipation of a subsequent discovery, unless it has been ascertained that the antecedent specification discloses a practicable mode of producing the result which is the effect of the subsequent discovery. Of course, the difficulty is to determine the facts. If those responsible for the suggestion under notice are prepared to do that of which, so far, there appears no indication, namely, to unfold a feasible plan of readily determining when a patent is impracticable or unworkable and when a later, though similar, patent is workable, without all the delays, heavy costs, and uncertainty incidental to a judicial investigation with expert evidence, &c., then they will assuredly be entitled to the thanks of the whole community.

The most effectual mode of weeding out impracticable and unworkable patents is by making all patents subject to annual payments. These need not be large. A patent having been in existence for four years, if it be not impracticable or unworkable, the owner would have no difficulty in providing, say, a couple of pounds to keep it in force for another year, and so on. Even assuming, for the moment, that the fees for fourteen years were reduced to £25, then, roughly speaking, £2 per annum would be a reasonable charge for renewing the patent, year by year, after the fourth year of its term.

A further proposal is that a new class of Letters Patent be introduced at a low fee, and arranged to protect articles where the protection sought is limited to one purpose. This, like other proposals, is crude and indefinite, and, therefore, difficult to deal with; but no doubt there are certain classes of inventions that do not come strictly within the provisions of the existing law, but which might advantageously be protected for a limited time. The difficulty is to satisfactorily define inventions of this character, and to differentiate them from such as come legitimately within the purview of the Statute of Monopolies as interpreted by the Courts.

LEGAL INTELLIGENCE.

Woodhouse and Rawson United (Limited).

Mr. Justice North has granted an order calling upon the Lord Mayor's Court Authorities to withdraw from possession of certain goods on the premises of Woodhouse and Rawson United (Limited), which were taken in execution under writs of fi. fa., a Receiver being in possession. In granting the Order his Lordship expressed the opinion that a gross contempt of Court on the part of the execution creditors had taken place, and costs of this action will have to be paid by them.

Last week at Brentford an action was brought by Mr. W. S. Sargeant, of Chiswick, against Mr. E. Edwards, for the recovery of a balance of £38 odd for work done on the steam launch "Lady Violet," and for insurance, &c. A counter claim by Mr. Edwards for £27 for services rendered in connection with the registration of patents was also tried. It appeared that Mr. Sargeant was engaged by Mr. Edwards to construct a steam launch to be worked by a specified engine, to be supplied by the defendant. After the launch was built considerable alterations had to be made, and it was to recover the cost of these alterations that Mr. Sergeant brought the present action. The defence was that the plaintiff had assigned his interest in a debt to Woodhouse and Rawson United (Limited), and to prove this the defendant was called, and stated that he had received a notice from the plaintiff to the effect stated. The defendant further stated that he had already settled with Messrs. Woodhouse and Rawson for various accounts for £65, which included the amount of the present claim. Ultimately Judge Bagshawe reserved judgment in the first action and in the cross action gave Mr. Edwards £15. 1s. 5d. and the costs of the action.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March* 24, 1893.

The Telautograph.—The private exhibition of Prof. Elisha Gray's telautograph, of which I spoke in my last letter, took place on Tuesday last simultaneously at the offices of the Gray National Telautograph Company in New York and Chicago, before numerous representatives of the press. At these exhibitions the actual distances covered were not great, as the messages were transmitted only between the various rooms of the Company in each building. Resistances, however, were introduced into the lines so as to make them as nearly equivalent as possible to a mile in length. All of the instruments were connected to a switchboard similar in all essentials to a telephone switchboard, through which they were inter-connected as desired. About one hundred representatives of the Press responded to the invitations to the New York office, and the result has been that the new invention has been well written up. The exhibition, while a success as far as it went, does not appear to satisfy the technical mind that the instrument will have a large practical use. While the reproduction was reasonably perfect, sufficiently so as to preserve the individuality of the handwriting, the transmission seemed to be slow and laborious and the action of the receiving instrument somewhat awkward. It is probably a fact that letters rapidly written cannot be faithfully reproduced, and that as far as speed is concerned there can be no comparison with the ordinary transmission by the Morse code. Since two circuits are required for the transmission of the rectilinear components of the curves, three wires are essential, which means a multiplicity of connections in the switchboard, already too complicated in telephonic installations. The impossibility of multiple transmission over the same circuits by the methods involved is another bar to its successful competition with the present methods of telegraphic communication. The expense necessarily attached to the installation of such circuits and their maintenance will prove an insurmountable obstacle to their general introduction. It has some special advantages, however, over other methods of communication, one of which is that the message is autographic and is recorded, and, where one is connected with the exchange, it may be received in his office during his absence and without the necessity of passing through the hands of a third party. It would seem, however, that its largest application would necessarily be between central offices and thence by means of a messenger to the party addressed. The instrument has been much simplified since Prof. Gray's first attempt, but, notwithstanding this, it seems to be capable of further simplification before it can become a commercial instrument, even in its most favourable field.

The Lamp Question.—The General Electric Company are continuing their crusade against infringing lamp manufacturers, as evidenced by two new applications for injunctions last week. These were against the Germania Electric Company and the Boston Incandescent Lamp Company, both of Boston, Massachusetts, to prohibit them from manufacturing incandescent lamps. It is a significant fact that the outside concerns now accept the past decisions as final, that both of these companies agreed to the issuance of injunctions, and that it should be made permanent. The Germania Company also at once made an assignment, and asked that a receiver be appointed to wind up its business.

CORRESPONDENCE.

HIGH VACUUM TUBES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I read with interest Mr. Rimington's article on "A Novel Electroscope" in *The Electrician* of March 24th. I discovered the effects of a charge of electricity on a vacuum tube about eighteen months ago. I then found that when a charged body was rapidly approached to, or withdrawn from, a vacuum tube, an instantaneous flash of light was the result, too faint to be seen, however, except in total darkness; but the denser the electrification the brighter the light, which also became more visible on increasing the rapidity of motion. To produce the best effects, I therefore revolved the tube by its centre in a perpendicular position at a high speed, which seems to be Mr. Rimington's method.

I also found that the same glow of light was induced in the tube by rubbing it on silk, flannel, &c.; and that if the tube was rubbed sideways along a long rubber, the light continued in intermittent flashes for about five minutes after removing the tube from the rubber, the flashes being about five seconds apart. If the tube is discharged by drawing a conductor along it, a succession of cracks is heard accompanied by flashes of light. An electrodeless tube was used, but an ordinary Giessler tube will produce the first effect; but the continued flashes are only seen in tubes of high vacua.—Yours &c.,

Greenwich, March 28, 1893. H. L. KERDEL.

A HYSTERESIS THEORY OF BROWN'S ALTERNATING-CURRENT MOTOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. J. A. Kingdon, in his article on "A Hysteresis Theory of Brown's Alternating-Current Motor," makes the curious assertion that the mathematical theory of alternate currents gives the current in the secondary in quadrature with the primary current. That this idea is erroneous may be simply shown thus. The differential equation to the secondary is

$$N\,dc_2/dt + M\,dc_1/dt + r_2 c_2 = 0;$$

where N is the self-induction of the secondary, M the mutual induction, r_2 the resistance of the secondary circuit; c_1 the primary and c_2 the secondary current. Assuming the currents as sine functions differing in phase, let $c_1 = C_1 \sin pt$ and $c_2 = C_2 \sin (pt+\theta)$, θ being the difference in phase between the two.

Then

$$p\,N\,C_2 \cos(pt+\theta) + p\,M\,C_1 \cos pt + C_2 r_2 \sin(pt+\theta) = 0.$$

$$C_2\{r_2 \sin(pt+\theta) + p\,N \cos(pt+\theta)\} = -p\,M\,C_1 \cos pt$$
$$= p\,M\,C_1 \sin(pt+\pi/2+\pi).$$

Hence

$$C_2 \sqrt{r_2^2 + p^2}\,N^2 \sin(pt+\theta+\phi) = C_1\,p\,M \sin(pt+\pi/2+\pi)$$

and this equation must hold for all values of t. Therefore

$$\theta + \phi = \pi + \pi/2 \text{ and } \tan\phi = pN/r_2,$$

$$\theta = \pi + (\pi/2 - \phi) \text{ and } \tan\theta = \cot\phi = r_2/pN,$$

Hosted by Google

If p N is large compared to r_2, ϕ will be nearly equal to $\pi/2$, but always less than it. Hence θ is nearly equal to π, but always greater than it, and θ is the angle by which the secondary current is *ahead* of the primary. It would, of course, come to the same thing to say that the secondary current lagged *behind* the primary by an angle rather less than π.

Of course, if the secondary circuit is open, the E.M.F. induced in it will be in quadrature with the primary current, as will be seen by making r_2 infinite, then tan $\phi = 0$ and $\phi = 0$. Hence $\theta = \pi + \pi/2$, or the secondary E.M.F. is $\pi/2$ behind the primary current. It must be remembered that this is not the current driving E.M.F. in the secondary, but that the E.M.F. of self-induction, which differs from it in phase, has to be subtracted.

With regard to the hysteresis question, if, as Mr. Kingdon tries to prove, the repulsion produced be due to hysteresis and not to the effect of self-induction, how does he explain the repulsion of wire rings and rotation of copper discs &c. when brought near an electromagnet excited by an alternating current (Elihu Thomson's experiments), since in this case the moving parts have no iron in which hysteresis can be developed? In all probability, as was pointed out in the editorial notes, the effect of the hysteresis is very small compared to that due to the self-induction, and there seems every reason to suppose that a motor constructed on these lines without iron at all would work, though of course feebly as the magnetic induction would be weak.—Yours, &c.

E. C. Rimington.

Lynton House, The Park, Norwood, S.E.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

Tenders Invited.—The Council of the Borough of Brighton require tenders for Lancashire boilers, steam and water system and piping, with feed pump; steam dynamos, and a motor-dynamo. Further particulars are given in our advertisement columns, and all information can be obtained of Mr. F. J. Tillstone, Town Clerk, Town Hall, Brighton. Tenders must be in by 10 a.m. on Monday, the 17th inst.

——— The Gas Committee of the Salford Borough Council invite tenders for the supply and erection of boilers, engines, electrical plant and mains, &c., for their electricity supply works. Some particulars appear in our advertisement columns, and full information may be obtained from Messrs. Kincaid, Waller and Manville, 29, Great George-street, Westminster, S.W. Tenders must be delivered to Mr. S. Brown, Town Clerk, before 5 p.m. on May 4th.

——— The Manchester Libraries Committee invite tenders for wiring and appliances for the electric lighting of the Free Reference Library, King-street, Manchester. Tenders must be in by April 15th. Further particulars appear in our advertisement columns.

——— The Corporation of Derby require tenders for the construction and laying of mains, and the supply of transformers, transformer boxes, lamps, posts, and accessories. Tenders must be in by the 17th inst.

——— Tenders will be received up to September 1st for the lighting by gas or electricity of the town of Szegedin (Hungary). Particulars can be obtained of the municipal engineer.

——— Readers are reminded that the tenders for the stock, plant, machinery and effects of an electrical and general engineering business, with patents, licences and goodwill, which has been established in the West Riding of Yorkshire for over fifteen years, and which is for disposal by Messrs. Lakeman and Oliver, must be in not later than Wednesday next, April 12th.

——— The French Direction des Postes et Télégraphes will, on the 13th inst., open tenders for creosoted telegraph poles, electric cables, tubes, curved and elbow-pieces, sleeve joints, junction pieces, and junction boxes. Information as to the schedule of prices can be obtained at the Third Bureau of the Division du Matériel et de l'Exploitation Électrique, 103, Rue de Grenelle, Paris.

Tenders Accepted.—Subject to certain deductions for simplification in the design agreed to by the Lighting Committee of the Cardiff Corporation, the tender of Messrs. W. Thomas and Co., of West Bute Dock, Cardiff, has been accepted for the construction of the chimney to be erected at the electric light works at Leckwith Common, the amount being £2,967.

——— The Electric Lighting Committee of the Whitehaven Trustees recommend the acceptance of the tender of Messrs. Siemens Brothers and Co. (Limited) for providing and laying the conductors for the Whitehaven electric lighting scheme. It is stated that a considerable saving will be effected on the contract originally entered into with the International Okonite Company (Limited), but which was rescinded a short time back.

——— The Electric Lighting Committee of the Bristol Corporation have accepted the tender of the Brush Electrical Engineering Company (Limited) for the equipment of the substations for the sum of £1,752.

Removal Notices.—The office of Elmore's German and Austro-Hungarian Metal Company (Limited) have been removed from 64, Cannon-street, E.C., to Broad-street-avenue, E.C. Mr. H. Ellis has been appointed secretary to the Company, *vice* Mr. J. Shurmer, who has resigned.

——— The Electrical Accessories Company (Limited) are removing their offices from 5, Macclesfield-street, Shaftesbury-avenue, W., to 110, Charing Cross-road, London, W.C., with works at Birmingham, as hitherto.

——— The offices of *Electricity* have been removed from Cannon-street to 29, Ludgate-hill, E.C.

Personal.—Mr. W. Farrar has resigned his position with the Corlett Electrical Engineering Company, Wigan, and has joined Messrs. Rosling and Matthews, of Trafalgar Works, Bradford.

——— Mr. C. N. Russell having resigned his position at Acton Hill, has been appointed engineer and manager to the London and Lancashire Electric and General Engineering Company, Limited, at Dalston, London, N.E.

Dissolution of Partnership.—Frank Reid and William Nichol, electrical engineers, Forth House, Bewick-street, Newcastle-upon-Tyne.

Bankruptcy.—The public examination of Edward James Bayly, electrical engineer, of 2, Selborne-street, Liverpool, lately adjudicated a bankrupt, is to take place at the Liverpool County Court on the 13th inst., at 11.——Frederick George Williams, lately trading as Kenyon and Co., electrical engineers, Crown Point, Denton, Lancs., has been granted his discharge, subject to the payment forthwith to the trustee of the sum of £193.

Lamp Shades.—Miss Overend, of Garville-avenue, Rathgar, Dublin, has recently designed a very ornamental lamp shade, particularly suitable for use with incandescent electric lamps. The shade is made up of crimped strips or ribbons of coloured paper representing floral combinations.

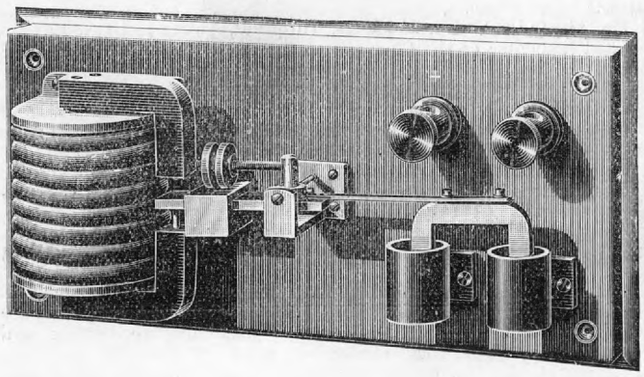
Messrs. Hodges and Todd.—This firm have just issued a new illustrated list of ammeters and voltmeters, battery cell testers, switch boards, resistance frames, &c.

Edison-Swan Price List.—The Edison and Swan United Electric Light Company have divided their price list into three sections, the first relating to lamps, the second to fittings, and the third to measuring instruments. Absence of competition has certainly not limited the number of varieties of lamps. Some 112 illustrations of lamps are given, most of them full size. The special lamps are sold, with but few exceptions, at the ordinary price. Among these special lamps we find some new forms of "focus lamps" for optical lanterns, from 8 c.p. to 200 c.p., the last being a formidable-looking affair. A number of flat lamps for portable reading-lamps are made. Double filament lamps for side lights of ships; lamps for chemical factories and gunpowder mills; long-necked flat lamps for exploring between the plates of a secondary battery; and a large number of fancy shapes are offered. Among a number of lamp holders of the most improved type, we find in Section II. the very earliest forms of wooden holders with spiral springs and outside terminals. That these are generally to be condemned few will deny; it is suggested in the price list that they are suitable for small, low-volt lamps. A considerable variety of switches and some complete switchboards are illustrated, and coloured plates of decorated porcelain fittings and fancy glass shades are given. Section III. contains gravity ammeters, and gravity, Cardew, and Fleming and Gimingham voltmeters, and a curious relic of bygone days, the Edison meter, to keep the wooden lampholders in company, perhaps.

An Automatic Accumulator Switch.—We illustrate below the latest form of the "Nevile" patent automatic accumulator switch, for which Messrs. Drake and Gorham are the agents for Great Britain. The switch is designed to prevent the current from a battery of accumulators from discharging itself through the dynamo when for any reason, such as a belt breaking or the gas supply of a gas engine being accidentally cut off, the E.M.F. of the

Hosted by Google

dynamo falls below that of the battery. Objection to this class of apparatus was formerly that springs were used in actuating them; or that they were so wound that during the whole time of working a small current was flowing from the battery through the instrument, causing waste and heating; or that it has generally been necessary to adjust them for one particular E.M.F., which has therefore been the highest one at which the battery was likely to be. Thus, when the apparatus was first started with the battery low it would not close the circuit until the dynamo was considerably above the battery in E.M.F., causing a jump in the lights, a



shock to the dynamo, and sometimes severing the main fuses by the large current generated. The "Nevile" apparatus is constructed somewhat on the principle of a polarised relay, and is so wound that so long as the E.M.F. of the battery is greater than that of the dynamo, the circuit is held open, but as soon as the E.M.F. of the dynamo exceeds that of the battery, the tendency of the switch is to move, a difference of 1 per cent. or 2 per cent. in the E.M.F. being sufficient to close the circuit, which is done by a copper fork dipping into two mercury cups. The opening or closing is effected when the E.M.F. on the two sides is practically the same, the current then passing being so small that, even with a switch constructed to carry 200 amperes, the spark is scarcely perceptible. The switch (printed instructions for fixing which are issued) has been considerably improved and modified lately, and can be obtained from Messrs. Drake and Gorham.

Barrow.—A Sub-Committee is to be appointed to consider and report to the County Council on the subject of applying for a Provisional Order empowering the Corporation to adopt and carry out a scheme of electric lighting for the borough.

Barry Dock.—Mr. F. J. Evans, the electrician to the Barry Railway Company, has successfully adapted the electric current to No. 12 coal tip at the Barry Dock Works, enabling 50 laden waggons to be drawn up to the tip at a time, an achievement which the old hydraulic method has never succeeded in accomplishing.

Birmingham.—The Birmingham Electric Supply Company have now reduced their rates to from 8d. per unit for supplies under 150 units down to 6d. per unit for above 600 units. These rates take the place of rebates previously allowed.

Birkenhead.—A sub-committee of the Town Council have under their consideration the question of the electric lighting of the borough, and strongly recommend the Council to carry out the provisions of their Provisional Order themselves. It was pointed out that unless the matter received the immediate attention of the Council their Provisional Order was in jeopardy, and the Board of Trade would be disposed to confer the powers upon a supply company to the exclusion of the Corporation.

Bournemouth.—The Town Council have been notified by the Board of Trade that should they decide upon lighting the gardens and pier by electricity a Provisional Order will be required. This could not be obtained this year, but a licence could probably be secured in about four months. The matter has been referred to a committee.

Cleckheaton.—A Local Government Board inquiry has been held in respect to the application for borrowing £5,540 for the Town Hall scheme, which includes a complete installation of the electric light.

Country House Lighting.—Goodrich Court, near Ross, Hereford, in the occupation of Mr. H. C. Moffatt, has recently been lighted by electricity. Two Spiel's patent oil engines, one of 10 and one of 2½ H.P., drive a 130-volt Goolden dynamo. The current is conveyed from the engine-room to Goodrich Court, a distance of 230 yards, through underground cables laid in bitumen casings up a very steep gradient, and charges a set of 54 Epstein accumulators, which store sufficient energy for from three to four days' ordinary consumption. The installation consists of about 250 incandescents, and the butler has sole charge of the controlling switches. The work has been carried out under the supervision of Mr. J. B. Cumberland, of Messrs. Rooper and Tozer.

Derry.—Notwithstanding an amendment that the matter of the electric lighting of the city should be postponed, the report of the Electric Lighting Committee was passed at the last meeting of the Corporation.

Dundalk.—The Town Commissioners have received a letter from Mr. T. M. Healy, M.P., stating that the Board of Trade are prepared to take into consideration the application for the renewal of the electric-lighting licence, which expires in July next, and which the Board had previously refused to renew. A special meeting of the Commissioners has been called to consider the subject.

Dundee.—The electric light is in considerable demand here, and an application has been made to the Works Committee to extend the lighting to the Dudhope-terrace district of the city. This would involve a further outlay of £2,000. It is probable that the Royal Infirmary will shortly adopt the electric light.

Falkirk.—A report has been presented to the Town Council by Mr. Neilson, their inspector, with reference to the proposed electric lighting scheme, in which he states that from inquiries he made he found that the engine plant at present in use for hydraulic purposes was insufficient for the electric lighting work, and he had therefore turned his attention to the utilisation of the water discharging into the Little Denny reservoir. He had consulted several engineers on the subject, and the result of his inquiries was that he had calculated that by using a turbine wheel at least 200 H.P. would be available for the purposes of electric lighting, and another turbine could be erected equal to a further 30 H.P. The estimate was rough, but he believed that the whole of the public lighting by electricity in the borough, including the public buildings, could be effected at an annual cost of about £500, including interest on capital, &c. During the past financial year they had paid for gas lighting purposes nearly £1,100. The report was remitted to the Lighting Committee for their consideration, with instructions from the Council to obtain from a firm of electrical engineers definite information on the subject.

Gartloch Asylum.—At the last meeting of the Glasgow District Lunacy Board it was decided to adopt the electric light for the new asylum which is being erected at Gartloch.

Guildford.—The Town Council have received the report of the Electric Lighting Committee regarding the proposed Provisional Order. The Committee advise the Council to withhold their consent to the granting of a Provisional Order to a private company, unless satisfactory terms can be arranged and a clause inserted arranging for the acquisition of the undertaking by the Council on reasonable terms. The Council have adopted the Committee's recommendations.

Halifax.—At a recent meeting of the Gas Works Committee of the Corporation in relation to an electric lighting scheme, the electrical engineer (Mr. Wilmshurst) reported favourably on the system of electric lighting adopted at Huddersfield, Bristol, Worcester, &c. Mr. Wilmshurst considers that the system adopted by these towns is economical, as is proved by the substantial dividends already being paid by companies working it. A warehouse recently occupied by the Salvation Army is suggested as the site for a central station; it is estimated that this building will accommodate sufficient plant and machinery for from 50,000 to 60,000 8-c.p. lamps. Mr. Wilmshurst recommends that high-pressure mains be laid throughout the main streets in the compulsory area, and that two sub-stations, one near the Town Hall and the other near the Post Office be erected. The total estimated cost of the plant recommended to be first put down is £23,600, and the ultimate cost of the scheme would be from £30,000 to £32,000.

Heckmondwike.—A public meeting was held last week for the purpose of again explaining the scheme for electric lighting here. There is to be an election of four members to the Local Board, chiefly on the electric lighting question, and the object of the meeting was to give those gentleman who are interesting themselves in bringing the matter prominently forward an opportunity of explaining their views. A resolution approving the scheme was unanimously adopted.

Hotel Lighting.—The *City Press* directs attention to the hesitancy shown by hotel keepers before adopting the electric light. One of the few hotels which now possess a complete electric lighting installation from cellar to top floor is the Cannon-street Hotel, London, E.C. This is one of the largest private lighting plants in London, and has cost nearly £5,000. The work of fitting and completing has been in progress for nearly two years. Mr. W. Durtnall has had charge of the entire installation, which, we understand, has proved completely successful. Great care has been taken to perfect every detail; the underground cables are run through glass-lined iron

Hosted by Google

tubes, and a connection is made with Mr. Durtnall's private room by which he is apprised of any accident during his absence from the generating room. At present there are only 1,000 lamps alight, but ultimately these will number between 1,400 and 1,500. It is more than likely that the cooking for the hotel will shortly be effected by electricity, and it is intended to run the laundry by electric instead of steam power. From a financial point of view the result is highly satisfactory.

HULL.—Mr. Holder, the Chairman of the Electric Lighting Committee, in referring to numerous applications for the electric light from residents and business men outside the district at present served, stated that the testimony of those who had used the electric light, not only for its saving over gas, but also for its general usefulness, had convinced those residing outside the area of the value of the light. It has been decided to circularise the district, and it is anticipated that a considerable extension of the light will ultimately be necessary.

ILFORD.—The Ratepayers' Association do not appear to be atis-s fied with the resolution of the Local Board to shelve the question of electric lighting for the present. A requisition has been made by the Chairman of the Ratepayers' Association to inspect the report of the expert employed by the Board, and the request has been acceded to.

LECTURES.—Amongst recent lectures on Electricity we note one by Mr. N. H. Watkinson on "Electric Welding," at Glasgow; by Mr. G. Fletcher, at the Derby Municipal Technical College, and also by Mr. J. Ritchie, at Edinburgh, on "Utilisation of Water-Power."

LOANHEAD.—The Shotts Iron Company have introduced the electric light into the Burghlee section of their colleries at Loanhead. The machinery is only partly employed at present, but it is ultimately intended to light the workshops, engine-houses, and the bottoms of the various pits. The Company contemplate extending the installation to their Ramsay colliery.

MOSS SIDE.—The works in connection with the electric lighting of this district are to be begun at once, and it is anticipated that the Whalley Range district will be lighted by next winter. The township is to have a telephonic exchange, the wires to be laid underground.

REDDITCH.—In connection with the renovation of St. Stephen's Church the authorities have under consideration the introduction of the electric light. Local rumours are to the effect that a supply company is shortly to be formed to serve the district.

SCARBOROUGH.—Mr. Bernard Drake, who is advising the Corporation, recommends this body to adopt the system of laying mains in cast-iron pipes with junction boxes, and also the use of the footpaths in preference to the carriage-ways for the mains.

SHEFFIELD.—Mr. John Tasker, owing to ill health, has resigned the Chairmanship of the Sheffield Electric Light and Power Company (Limited), and Mr. George Franklin has been elected Chairman in his stead. Mr. W. S. Laycock will fill the vacancy on the Board.

TIVERTON.—A special report by Mr. J. Siddalls, surveyor to the Town Council, on the proposed electric lighting scheme for the borough has been printed and will shortly be issued.

TUNBRIDGE WELLS.—In reference to the subject of introducing the electric light at Tunbridge Wells, considerable correspondence has appeared in the local press, and reference has been made from time to time to the lighting of the City of London. Sir David Salomons, in a recent letter on the subject, points out a number of advantages which the electric light has given to the City which have not been fairly stated in the correspondence that has appeared, and he refers to a breakdown which recently occurred, and which, although it only lasted for eight minutes, was sufficiently serious. In digging the trenches for the permanent works, some of the pipes containing the cables from the pioneer station were exposed, and one of the stokers, instead of throwing the hot ashes from a boiler furnace into the usual receptacle, thought it more convenient to throw them into the open trench in which were the exposed pipes, with the result that the insulation on the cables was melted. This sufficiently explains an incident of which those opposed to the introduction of the electric light at Tunbridge Wells have made much.

WAKEFIELD.—In the estimates accompanying the plans for lighting the new offices of the County Council, provision is made for the electric light. A number of business men in the city have also the question of lighting their premises by electricity under consideration.

WEST HAM.—The Works Committee of the Town Council, in presenting their last report, state they have further considered the subject of electric lighting in the borough, and that they recommend the Council to put in force the Provisional Order obtained in June last, and proceed to carry out the scheme for lighting the principal streets of the district.

RE WOODHOUSE AND RAWSON UNITED, LIMITED.

At the moment of going to press we have received a circular signed by Sir Rawson W. Rawson and Mr. Samuel Pope, Q.C. (dated 5th April), an abstract of which we give below :—

As trustees for the Debenture Stock of this Company, we are advised that it is our duty to call a meeting of the stockholders with a view to their considering the present position, and their course of action in the future. We think it best, also, to invite the attendance of all the other creditors of the Company, whether secured or unsecured, at the meeting which we propose to call, with a view to taking their opinion also as to what should be done.

Mr. Alexander Young, of Messrs. Turquand, Young and Co., was appointed liquidator of the Company at the recent General Meeting, and Mr. F. D. Leslie, of Messrs. Robinson and Leslie, has been appointed by the Court Receiver of the Company's assets and manager of the business, as representing all the secured creditors.

Petitions have also been presented against the Company to wind it up compulsorily, one by a debenture holder for an amount of £250, and the other by a creditor for £185. and, as they will come on for hearing on the 11th April, it is important that the views of the creditors should be represented before the Court.

A meeting will, therefore, be held of all the creditors of the Company on Monday, the 10th inst., at 12 o'clock, at the Cannon-street Hotel, E.C., at which we shall shortly lay the facts before the creditors, with the object of their views being represented on the hearing of the petitions. Now that the liquidator has been appointed, the Directors have no responsibility for the further management of the Company's affairs, but are desirous of a reconstruction scheme being carried out, which will not only save some of the shareholders' money, but will enable the creditors to be paid in full. It is to the interest of all creditors to attend the meeting.

On the one hand it is suggested that a hasty and immediate realisation of the Company's assets under a compulsory winding-up will probably result in a heavy loss even to the secured creditors; and, on the other hand, it is believed by many of those interested in the Company that a reconstruction scheme may be carried through which will not only pay all the creditors in full, but leave a substantial balance for the shareholders. We cannot give details of the scheme, which is, we understand, at present before counsel, but we are able so say that the outline of the scheme is as follows :—

1. That a new Company be formed under a new Board of Directors, to be subsequently appointed by the subscribers, for the purpose of carrying on so much of the business of the old Company as promises to be profitable, and constituting a channel through which the assets may be advantageously realised.

2. That the receiver of the Company's assets will not part with any of those assets to the new Company proposed to be formed without receiving cash, or unquestionable security to the value of the assets so to be transferred to the new Company.

3. That any new money to be found as working capital for the new Company shall not be subject to the liabilities of the old Company.

4. That the sum of £25,000 be provided as working capital of the new Company, this sum to be raised either from shareholders or from other persons outside the Company, who will receive as consideration for finding this money bonds or other securities entitling them to a preferential claim upon the profits of the new Company.

5. The proceeds of the assets sold to the new Company or others will be distributed by the Receiver to the creditors of the old Company according to their priorities.

6. The new Company will assist the Receiver in realising those assets of the old Company which can be utilised in the business of the new Company by the way of fulfilling their contracts, and in the ordinary course of trade.

7. Those portions of the Company's premises which are especially suitable for the trade which will be carried on by the new Company will be leased to the new Company.

We are extremely anxious that all the creditors of the Company should attend the meeting of which we have given you the above notice, but in the event of your being unfortunately unable to do so, we shall be glad to know your views, whether favourable or adverse to a scheme of reconstruction based upon the above principles, and we shall be much obliged if you will return to us the form enclosed, signing the same, and altering it to suit your views, if you are opposed to the scheme. Fuller particulars will be given at the meeting, and later on the reconstruction scheme will be laid before you in its entirety.

COMPANIES' MEETINGS & REPORTS.

Elmore's French Patent Copper Depositing Company (Limited).

The following circular letter has been issued by the Directors of this Company, accompanying the statement of accounts referred to :—

"Herewith we beg to send you accounts made up to December 31st last. From these you will see that the total amount of working capital that the Company have had at their disposal at the date of the balance-sheet from shares and debentures, after paying for patents, has been £140,061. In addition to this, the Company have had upon second mortgage £39,353,

Hosted by Google

and from loans the sum of £28,789, and have incurred further liabilities amounting to £21,761. This sum has been expended as follows :—(1) Cost of land, buildings, plant, furniture, stock, cash in hand and other assets, £169,458. (2) Expenses of issue of preference capital, £3,334, which would, in the ordinary course, be spread over a series of years. (3) Expenses up to May 31, 1892, connected with the establishment of the Company, the working out in the laboratory and works of the details of the process and alterations connected therewith, and in connection with the new patents taken out by the Company, £18,483, the major portion of which could be either put to capital account, or the whole extended over a series of years. (4) Administration charges in Paris and London up to May 31, 1892, which might be spread over a term of years, but which it would be more prudent to write off at once—namely, £14,416. (5) The amount paid by the Company as interest and commission, £4,165, after deducting interest received on deposits, £609, which must be written off. (6) With regard to the bonus credited, but not yet paid, to the Foreign Company, namely, £3,000, this, the Directors hope, will be waived. (7) The remaining items for rent of water-power and loss by exchange on sending money to Paris amount to £1,256. The profit and loss is taken from June 1 to December 31, 1892, which is the time that the Company has been at work regularly. It may be recollected that Sir Frederick Bramwell and Mr. Harris estimated that 12½ tons per week would pay all expenses. Owing to the small output during this period, namely, about 7 tons per week, the loss in manufacturing amounts to £5,187. Of this there is a certain amount of copper existent in the furnace bottoms, which is recoverable when these furnaces are ultimately taken up, though in the accounts treated as loss. The total administration expenses in France during this period amount to £2,972, and in London to £2,427. These charges are increased beyond the normal by incidental expenditure and professional charges, travelling expenses, &c. The amount of interest and commission comes to £4,884 for the same period, whilst the interest on debentures comes to £1,750, and the rent of water-power at Bellegarde to £1,687, The Directors consider that in normal working the administration charges in Paris and London ought be covered by £5,000 per annum, unless the business is carried on on a much larger scale than is proposed. Naturally, at the outset of the Company heavy expenses have had to be incurred under this head."

A circular has also been issued, signed "Maddisons," in which exception is taken to the "share holdings" of the Committee of Investigation recently inquiring into the affairs of this Company, consisting of Messrs. Saunders, M.P., and Storey, M.P., and Sir Thomas Farrer. Mr. Storey, in reply, states that he holds a considerable number of shares in the Company, the bulk of which cost him 2¾, and none less than 1¾, and he further states that the object of calling the recent meeting was to put a stop to the extravagant daily loss, and to secure what he could for himself and his co-shareholders. Mr. Burnside, who was selected as financial expert to assist the Committee in their investigations, has (Mr. Storey states) never bought, sold or held a share in the Company at any time.

An extraordinary general meeting of this Company was held yesterday at Winchester House, E.C., Major Jones in the chair, to consider, and if approved, pass the following extraordinary resolution :—

"*That it has been proved to the satisfaction of this meeting that the Company cannot, by reason of its liabilities, continue its business, and that it is advisable to wind up the same, and accordingly that the Company be wound up voluntarily.*"

The SECRETARY (Mr. J. Shurmer) having read the notice calling the meeting,

The CHAIRMAN stated that the meeting had been called in fulfilment of an undertaking given by the Directors at the recent informal meeting of certain shareholders. At that time the Board expressed their opinion, which they still held, that the shareholders, in their own interests, should unite and carry out the policy advocated by the Directors—namely, the issue of £100,000 new Debenture Stock, wherewith to pay off the existing £50,000 of Debenture Stock, and to provide the necessary capital for meeting the liabilities of the Company and carrying on its work. About £9,000 had been actually subscribed, and more had been conditionally promised ; but, unfortunately, the action taken by Messrs. Saunders and Storey had prevented their having any chance of carrying out the scheme. A petition had been filed for winding up the Company, which would come on for hearing on the 11th inst., as they ascertained on returning to the offices from the informal meeting referred to ; and since then, acting on the part of one of the largest shareholders, Mr. Wood—and, he believed, in the interest of the shareholders generally—Messrs. Maddison had put in a receiver, Mr. Duncan, who had been to Paris, where he had investigated the Company's affairs. and had interviewed the general manager, M. Sécretan. He asked Messrs. Saunders and Storey to put the meeting in possession of their views as regarded liquidation.

Mr. STOREY, M.P., stated that the meeting had been called for a specific purpose, and it was the Chairman's duty to propose the resolution, of which notice had been given.

The CHAIRMAN stated that the Directors agreed to call the present meeting, but they did not undertake to recommend voluntary liquidation.

Mr. MADDISON stated that since the last meeting the situation had greatly changed. It might be wise not to decide to go into liquidation at that meeting. He suggested that the meeting should be deferred until the 10th instant, to see whether M. Secrétan could be brought to make a definite offer to them.

Mr. J. H. DUNCAN stated that since his appointment as Receiver he had been to Paris, where he had found an exceedingly critical financial position, and there was a threat on Good Friday of a French liquidator taking possession of everything. If that were done, the position for the shareholders, and even the creditors, on this side would be a very disastrous one. As regarded the receipt of orders, as far as he could judge, there was a distinct encouragement. He had seen gentlemen in Paris who held about 5,000 shares, and he asked them particularly as to the reputation which the business enjoyed. The answer he received was that as regarded the financial position, it was extremely bad, but that nothing could be better than its industrial and commercial position. He could not contemplate how the Company could possibly be carried on without more working capital being provided than he had yet heard mentioned. He himself could not but be struck with the point that to carry on the business on a small scale meant loss, on a moderate scale it would mean just paying expenses ; while if they got up to a certain figure they would show some profits, and if they went past that figure they would begin to make large profits. Placed as he found himself in Paris, he approached M. Secrétan on the lines of the offer made by that gentleman to the Directors. If they authorised negotiations being entered into, he believed that M. Secrétan would agree to a proposal by which a French Company or firm would be formed, which would raise £80,000 or £100,000 in Paris. Out of this sum they would pay £20,000 to the English Company to get rid of their liabilities in France, amounting, he believed, to about £7,000 or £8,000 ; they would give £50,000 in obligations forming a first charge on the undertaking, bearing 5 per cent. interest, but issued at a discount so as to yield 6 per cent.; and they would also issue £60,000 of founders' shares to rank after the capital raised in Paris. He told M. Secrétan, however, that he must allow the old shareholders to come in for 10 per cent. immediately after the working capital had had 10 per cent., half of the surplus to go to the £60,000 of founders' shares belonging to the shareholders, and the remaining half to the capital raised in France. It struck him that if they had not the courage on this side to find the means to carry on the Company, their friends in France should be allowed to do so. If they could keep the Company alive and settle with their creditors on the basis of the plan shadowed out, he thought the Company could be resolved into something like a simple trust. M. Secrétan told him that out of the Committee of Control of five, two would be appointed on behalf of the English shareholders and three on behalf of the French proprietors.

Mr. STOREY, M.P., said that by the proposal outlined by Mr. Duncan all the cash which the Company would receive from France would have to be paid away to creditors, and they would then remain in debt to the extent of between £20,000 and £29,000, with no cash in hand; secondly, that the obligations offered to them would practically have to go to the debenture-holders here ; and thirdly, that of the £60,000 of founder's share, the preference shareholders' shares would be £43,000. There would thus be left for the £100,000 of ordinary shares, £17,000 of founders' shares, of no value on the market, upon which M. Secrétan might be able some day to give them something, after he and his friends had got 10 per cent. For this they would have to give up the whole of their property to M. Secrétan, and he (the speaker) was decidedly averse to any such proceeding. There was a petition filed, to be heard on the 11th, for winding up the Company compulsorily, and if they did nothing the petition would be heard and granted, and the Company would be compulsorily wound up, when no one would get anything. He had made a proposal that they should go into voluntary liquidation, under the control of the Court, so that they might stop the existing expenditure, and be in a strong position to negotiate.

Mr. F. L. RAWSON said he presumed that the object of Mr. Duncan in suggesting a postponement was that the details of the scheme might be worked out. All their difficulties, if faced, melted away.

Mr. MADDISON proposed a resolution adjourning the meeting until Monday next at the same time and place.

The motion having been seconded,

The SECRETARY said that he had received a letter from Sir Thomas Farrer. It was clear that that gentleman did not by any means endorse the reports or the recommendations emanating from Messrs. Saunders and Storey. He read the letter, in which Sir Thomas Farrer also said that his opinion had been for some time that the financial position of all the Elmore Companies needed investigation.

Mr. SAUNDERS, M.P., afterwards addressed the meeting, and moved an amendment to the effect that they should now pass the resolution for voluntarily winding up the Company under the supervision of the Court.

The CHAIRMAN intimated that the amendment was out of order.

Mr. STOREY said that he desired to protest against the Chairman's conduct at the meeting, in view of eventualities. With regard to the remarks of Mr. Rawson, he had declined, and he still declined, to enter into any communication with that gentleman about any of the Elmore Companies ; and his only hope was that before they had done with them there would be a public exposition of all the facts with regard to the financing and getting up of the Companies.

The CHAIRMAN then put the motion for adjourning the meeting, and declared it carried.

Johannesburg Lighting Company (Limited).

The second ordinary general meeting of this Company was held yesterday at Winchester House, Old Broad-street, Mr. W. Garland Soper presiding.

The SECRETARY read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN, in moving the adoption of the report and accounts, said that it would be within their recollection that the Lighting Company took over the Gas Company, the consideration being one share in this Company for two shares in the Gas Company, preference shares at par in this Company for debentures in the Gas Company, and in addition 20,000 shares in this Company, of which 7,868 shares were still unissued. The figures recording the assets in the balance-sheet agreed with the above

Hosted by Google

purchase price of the Gas Company, but in the opinion of the Board the assets were entered below their value. He must also remind them that although the revenue account covered a period of ten months, yet lighting had not been supplied for the whole ten months. As a matter of account there appeared a loss, but as a matter of value this loss they considered more than covered—there was in their judgment more than 20s. in the £. The expenses were necessarily heavy, but as the consumption of electricity and gas increased, the relative proportion of expenses to revenue ought materially to diminish. As to the supply of electricity they might say that by the introduction of electrometers consumption was measured with economy to the Company and with satisfaction to the consumers. The demand for this light was in excess of the quantity they could supply. But the fact was that the Company was becoming unequal, as now constituted, to meet the present and increasing demands for light which were arising both for gas and electricity, and which by virtue of the concession they held they ought to be ready to furnish. In addition to the town itself there were the districts of Doornfontein and Jeppestown, which in themselves were important suburbs, and which they were under contract to at once supply with light. They, therefore, must have more capital. This money was required for the transport and erection of the second gas holder and tank and extending the mains and the supply of further plant for the electric lighting to Doornfontein and Jeppestown and other extensions of the system which were very urgent. The present indications of revenue based on actual working were these:—On gas without the products, and on the present supply by only one gasholder, a net profit of £3,600 per annum, as by a statement made by Mr. Lance under date February 24, 1893; on electricity without the present No. 3 plant (on February returns), £2,280 per annum, To meet their difficulties and cope with the growing demand for light, the Directors suggested that the shareholders and debenture holders should consent to the issue of debenture *pari passu*, but not preferent to the existing £60,000.

Mr. W. M. FARMER seconded the motion.

The CHAIRMAN, in reply to Dr. Todd, said that all the figures he had given were based on the actual working at the present moment, with their coal costing £3 per ton. Johannesburg was going ahead at a rapid pace, and the demand for artificial light had been greater than the Company had been able to supply.

The motion was then agreed to *nem. con.*

The CHAIRMAN next proposed a resolution approving the proposal of the Directors to borrow a sum not exceeding £40,000 on debentures. Whoever subscribed to these debentures would not subscribe money to defray liabilities, because there were practically no liabilities to pay, for all of which there was sufficient cash in hand. The money was required simply to supply new material and new stock.

Mr. S. HUGHES HEWITT seconded the motion, which was carried unanimously.

The retiring Director, Mr. W. Garland Soper, was, on the motion of Mr. ALFRED JONES, seconded by Mr. WILLS, unanimously re-elected to his seat at the Board.

The auditor, Mr. W. F. Turner, was also re-appointed on the motion of Mr. WALLIS, seconded by Mr. KERRISON, and a vote of thanks having been accorded to the Chairman, the proceedings ended.

Hobart Tramways Company (Limited).

An extraordinary general meeting of this Company was held yesterday at the offices, College Hill-chambers, E.C., under the presidency of Mr. Alfred Mattei, L.L.D., to consider a resolution altering the name of the Company to the Hobart Electrical Tramways Company. The Chairman said the proposed alteration was made at the request of some of the largest shareholders, and the Directors after careful inquiry had found that they were well within their powers in acceding to the proposal. They had the advantage of having present at the meeting their engineer, Mr. Harper, who had been over the line and had expressed satisfaction at the manner in which the contract had been carried out. It was a matter of regret that the line had not yet been opened for traffic, but their Tasmanian friends were doing all in their power to accelerate matters. The electrical work had been carried out by Messrs. Siemens Bros. and Co. of London. The material had been sent out from England and it had been thoroughly inspected. Sir Benjamin Baker had expressed great satisfaction with the cars, dynamos, and all he had seen. Hobart was a rising place, and the P. and O. and Orient Companies both sent their boats to the port during the fruit season. The latest news from the Mount Zeehan Silver Field on the West Coast was of a very satisfactory character. At present Hobart was the principal route for the West Coast viâ Strahan, and, therefore, this Company would also benefit by the development of those fields. In reply to a question, he stated that the Board were still in correspondence with the Tasmanian Government in reference to Sir Edward Braddon continuing to occupy the position of Chairman of the Company, because it had been brought out under his auspices, and no one could better serve the interests of the shareholders than Sir Edward, because of his great ability and local knowledge. A resolution in accordance with the object of the meeting was agreed to, and a vote of thanks to the Chairman closed the proceedings.

City of London Electric Lighting Company (Limited).

The following Directors' report is to be presented at the third ordinary general meeting of this Company, to be held at Winchester House on Thursday, the 13th inst., at 2:30 p.m.

The revenue account is for six months only, the period previous to June 30, 1892, having been occupied principally in testing under continuous running the first plant delivered by the contractors.

The expenditure on capital account up to December 31, 1892, amounted to £448,163. 12s. 9d. The greater part of this outlay is for land and for conduits and similar works which have not yet been fully utilised, but which are necessary for the proper carrying out of the Company's business as its operations extend.

The gross revenue for the six months was	£10,425	11	2
The expenditure, including the loss on the public lighting, was	9,991	4	7
Leaving a net revenue of	£434	6	7

The sums payable by the New Telephone Company (Limited) in respect of tubes agreed to be leased under the provisions of the Telegraphs Act, 1892, are not included in the accounts.

In view of the fact that the Company has not finally accepted the plant from the contractors and that all other works are still in progress, the question of depreciation does not at present arise, but the necessary provision will be made in due course.

The revenue is daily increasing, and is now being earned at the estimated rate of £35,000 per annum gross. The Directors consider this result satisfactory when it is remembered that the Company can scarcely be said to have fairly got to work.

The first section of the main engine and boiler house, with one of the large chimney shafts, at Bankside is practically complete, and the machinery is in course of erection. The second section is being actively pushed on with. Eighteen sites have been secured for transformer substations, of which four are in operation and six in course of construction. The remainder will be proceeded with during the current half-year. Each station when fully equipped will be capable of supplying energy to at least 20,000 8-c.p. lamps. The erection of machinery is being rapidly proceeded with. The plant already in position and on order, which it is expected will be erected before the end of the year, will be sufficient for 140,000 8-c.p. lamps. The arc-lighting plant installed is fully equal to all demands for public lighting. The number of units sold during the half-year was 506,400.

Street work has progressed satisfactorily. On December 31, 1892, 371 miles of "ways" had been laid in the City, and this length has since (this report is dated March 23rd) been increased to 415 miles, into which 95 miles of cables have been drawn. Sufficient "ways" have been laid down to supply an ultimate demand of 400,000 8-c.p. lamps. Future expenditure will, therefore, be chiefly confined to outlay on cables, which will only be incurred as applications for lamps are received. Work will be commenced in Southwark as soon as the Company's plans have been approved by the local authority.

On December 31, 1892, out of the equivalent of 53,000 8-c.p. lamps for which signed applications had been received, 20,250 had been connected up and service lines for 12,500 had been practically completed. The applications have since increased to 66,500 and the connections to 34,000, while additional applications continue to come in at a satisfactory rate. By the end of the present year the Company will be able to supply current throughout the City area.

All the arc lamps in the main thoroughfares are erected and running, with the exception of a few for which positions have not yet been assigned by the Commissioners of Sewers. The Company is ready to commence the lighting of the lesser thoroughfares, but the City authorities have as yet only given the order to proceed with two streets with lamps of different candle-power to test their relative efficiency.

The Directors regret that through the death of the Duke of Marlborough they have lost a colleague who always took a keen and intelligent interest in the business of the Company. In accordance with the Articles of Association two of the Directors, Joseph Bevan Braithwaite, jun., and Frederick W. Reynolds, retire, but being eligible, offer themselves for re-election; and the auditors, Messrs. W. H. Pannell and Co., also retire, and, being eligible, offer themselves for re-election.

Eastbourne Electric Light Company (Limited).

The following is the report of the Directors to be presented at the next ordinary general meeting of the Company:—

The Directors in presenting the accounts of the Company for the year ended December 31, 1892, congratulate the shareholders upon the fact that, for the first time since the Company's incorporation, a sufficient profit has been made to permit of a dividend being paid upon the ordinary shares. This is due to the steady increase of the Company's business, coupled with the exercise of proper economy in the working of the concern. The profit available for dividend is £431. 7s. 2d., and out of this the Directors suggest that £3 per cent. per annum shall be paid upon the subscribed share capital as for the year ended December 31, 1892. This will absorb £317. 2s., and will leave a balance of £114. 5s. 2d. to be carried forward as a reserve. The Directors have purchased the freehold of works in Junction-road for £5,600. This will explain the heavy outlay on capital account on the one side and the overdraft at the Bank on the other. A considerable saving in rent has been effected by the purchase. The Directors have now under consideration the extension of the circuits to the Upperton district, where they have ascertained the light is greatly desired. They have also accepted a contract with the Corporation for increased arc lighting on the sea front, and other extensions of the Company's business can now be entered upon to great advantage. But this increase of business will need additional capital, and a prospectus for this purpose will shortly be issued. The whole of the Company's plant, machinery, and mains are in excellent condition. Mr. George Boulton retires from the Directorate this year, but is eligible for re-election. The auditors, Messrs. Hart Brothers, Tibbetts and Co., also retire, but may be re-elected.

NEW COMPANIES, STATUTORY RETURNS, &c.

CALDWELL'S (LIMITED).—Capital £12,000, in £10 shares. Smiths, mill and colliery furnishers, mechanical and electrical engineers, electricians, &c., of Horsemarket-street and Scotland-road, Warrington.

COMPAGNIE FRANCAISE POUR L'EXPLOITATION DES PROCEDES THOMSON-HOUSTON.—A company with this title has recently been formed, with offices in London. The capital is 1,000,000fr.

DOMESTIC TELEPHONE COMPANY (LIMITED).—This Company was registered on April 4, 1893, with a capital of £20,000, divided into 3,990 ordinary, or "A," shares of £5 each, and 10 management, or "B," shares of like value, to enter into and carry into effect an agreement to be made between Sir Charles Stewart Forbes, Bart., and the Company, to acquire, develop, and manufacture, in accordance with certain inventions and patents, and any other inventions, patents, or other rights that may be acquired by the Company, and to carry on in the United Kingdom and elsewhere the business of a telephone company and exchange, electrical engineers, electricians, and manufacturers of all kinds of electrical, telephonic, or magnetic appliances used in connection therewith. The signatories are :— A Shares.

Sir Charles S. Forbes, Bart., 28, Queen's Gate-terrace, W..	1
James Mansfield, 29, St. James's-place, S.W.	1
Joseph R. Gibson, 312, Kennington Park-road, S.E.	1
C. Harrison, 67, Lincoln's Inn-fields, W.C.	1
Claude Hay, 28, Cornhill, E.C.	1
Thomas D. Croft, 17, Dorset-square, N.W.	1
Louis T. Fitzgibbon, 22, Harrington-road, S.W.	1

The first Directors are Sir Charles S. Forbes, Bart., the Hon. James Mansfield, the Hon. Claude Hay, Louis T. Fitzgibbon, and Thomas D. Croft. No qualification necessary.

HUMBER LAMP COMPANY (LIMITED).—Capital £5,000, in £1 shares. Dealers in lamps of all kinds, electric and otherwise, of Great Grimsby.

NEWINGTON, PRIDDLE, AND CO. (LIMITED).—This Company was registered on March 29th with a capital of £7,000 in £1 shares. The objects are to acquire, develop, and turn to account certain inventions, licences, privileges, and rights (the further particulars of which are not given) to be acquired on the adoption and acceptance of an agreement dated March 28, 1893, and made between Reginald W. H. Newington and Edward Priddle, of the one part, and Robert Hail (on behalf of the above-named Company) of the other part, and to carry on the business of electrical and general engineers. The first two signatories are Reginald H. Newington, electrical engineer and Edward Priddle, mechanical engineer, both of 4, Berry-street, Clerkenwell, London, E.C., who are also the vendors.

SOCIETE PAUL GADOT ET MICHEL PISCA.—Under this title a company has been formed, with offices in Paris, to carry on the manufacture of accumulators. The capital is 90,000fr.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).—The annual return of this Company made up to February 10, 1893, has been filed. The whole nominal capital of £7,000,000 stock is fully paid up.

BIRMINGHAM TELEGRAPH FACTORY (LIMITED).—A petition has been presented by Messrs. Alabaster, Gatehouse and Co. for the compulsory winding up of this Company, now in voluntary liquidation. The petition will be heard at the County Court, Birmingham, on Thursday next, the 13th inst.

BLACKPOOL ELECTRIC TRAMWAY COMPANY (LIMITED).—A meeting of the shareholders is called for May 3rd, at twelve, at Messrs. Godfrey, Rhodes and Evans's, Commercial Bank-chambers, Halifax, to receive an account of the winding up.

CAMBRIDGE ELECTRIC SUPPLY COMPANY (LIMITED).—The first annual return of this Company, made up to March 17th, has been filed. 2,306 shares, out of a capital of £50,000, in £10 shares, have been taken up, and a call of £8 per share made, resulting in the payment of £17,922, and leaving £526 as yet in arrears.

ELECTRICAL SUPPLIES AND FITTINGS COMPANY (LIMITED).—Claims against this Company, in voluntary liquidation, are to be sent to Mr. John Scott, 8 and 10, Charing Cross-road, by the 25th inst.——A petition has been presented by the Electrical Company (Limited) for the compulsory winding up of the Company, and is down for hearing at the Royal Courts of Justice, Strand, on Tuesday next, the 11th inst.

ELMORE'S FRENCH PATENT COPPER DEPOSITING COMPANY (LIMITED).—A petition has been presented by the Loan and Finance Corporation (Limited) for the compulsory winding up of this Company, and is down for hearing at the Royal Courts of Justice, Strand, on Tuesday next, the 11th inst.

HOPE-JONES ELECTRIC ORGAN COMPANY (LIMITED).—The statutory return of this Company, made up to November 8, 1892, has been filed. The nominal capital is £25,000, divided into 1,200 cumulative preference and 1,300 ordinary shares of £10 each, 445 cumulative preference and 1,300 ordinary shares have been taken up, of which the ordinary shares have been issued as paid to Robert Hope-Jones, of Argyle-street, Birkenhead, electrician (1,000), and Thomas Threlfall, of 19, Hyde Park-terrace, W. (300). Upon 20 of the preference shares the full amounts have been called, while upon the remaining 425 preference shares, £5 per share has been called, resulting in the payment of £2,325.

JULIUS SAX AND CO. (LIMITED).—The statutory return of this Company, made up to March 14th, has been filed. The whole nominal capital of £20,000, in £10 shares, has been taken up, of which 1,993 shares were issued as fully-paid. Nothing has been paid on the remaining 7 shares.

L. ALWYN (LIMITED).—The statutory return of this Company, made up to March 22nd, has been filed. The nominal capital of the Company is £2,000, in £1 shares. At the time of making-up, 1,514 shares were taken up, of which 500 were issued as half-paid. Upon the remaining 1,014 shares, 10s. per share has been called, resulting in the payment (including a sum of £2 in advance) of £509.

NORTHAMPTON ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of this Company, made up to March 9, has been filed. The nominal capital is £50,000, divided into 10 "A," 49,990 "B" shares of £1 each. Ten "A," 10,000 "B" ordinary, and 3,180 "B" preference shares have been taken up. Upon the 10 "A" shares no calls have been made; upon the "B" ordinary shares the full amount has been called and all calls paid, and upon the "B" preference shares 10s. per share has been called, and £2,875 paid (including sums paid in advance of calls).

NORTHERN ELECTRIC WIRE AND CABLE MANUFACTURING COMPANY (LIMITED).—The fourth annual return of the above-named Company, made up to March 20th, has been filed. The nominal capital is £20,000, divided into 660 fully-paid and 3,340 ordinary shares of £5 each. All the fully-paid and and 2,167 of the ordinary shares have been taken up, of which the fully-paid have been issued to Blakey, Emmott, and Co. (Limited), of Halifax (now in voluntary liquidation). Upon the ordinary shares £2. 10s. per share has been called, resulting in the payment of £5,415, leaving £2. 10s. unpaid.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LTD.),—The annual return of this Company, made up to March 14th, has been filed. The nominal capital is £448,200, divided into 37,350 shares of £12 each. All these shares have been taken up, the full amounts called, and all calls (£448,200) paid.

TELEPHONE COMPANY OF AUSTRIA (LIMITED).—Claims against this Company, in voluntary liquidation, must be sent in to the liquidators at 53, Old Broad-street, E.C., by May 6th.

WOODHOUSE AND RAWSON ELECTRIC SUPPLY COMPANY OF GREAT BRITAIN (LIMITED).—A meeting is to be held at the office of the Company, Room 433, 11, Queen Victoria-street, E.C., on May 1st, at 4 p.m., to receive an account of the winding up.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended April 2nd were £744, as against £796 for the corresponding period of last year, being a decrease of £52. The total receipts for half-year amount to £12,014 against £11,019 in the corresponding period of 1892, being an increase of £995.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of March were £4,200, as compared with £4,038 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The traffic for the half-year ended December 31st last.—The traffic receipts for the month of March were £2,015, against £2,103 for the corresponding period of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of March amounted to £55,786 and to £59,037 in the corresponding period of 1892.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of March, 1893, amounted to £46,204, and to £43,805 in the corresponding period of 1892, or an increase of £2,399.

THE ELECTRIC LIGHT IN CANADA.—It is stated that a syndicate, having its head-quarters in Montreal, has obtained a controlling interest in the Ottawa Gas Company and the Ottawa Electric Light Company for $500,000. The syndicate has a bill before the Dominion Parliament to enable them to buy up and amalgamate all the gas and electric light companies in Canada.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for March amounted to £22,000, and from January 1st to March 31st to £63,200. In the corresponding months of 1892 and 1891 the amounts were £62,800 and £64,400 respectively.

NEW AUSTRALIAN ELECTRIC COMPANY (LIMITED).—A meeting of the shareholders of this Company was held on February 20th, at the offices, Melbourne. Prof. W. C. Kernot, who presided, said that the general position of the Company was certainly satisfactory, and they had been making steady progress during the past year. Their lighting business had not been extended very much, but it had been consolidated. Their financial position on the whole was also very satisfactory. Their total capital called up was, say, £22,000, whilst their assets amounted to between £70,000 and £80,000—that was to say, their two lighting stations, the plant, machinery, and stock were worth over £70,000. As a matter of fact, the capital on which they were working was very much larger than their subscribed capital, and consisted, to a considerable extent, of loans on mortgage—£35,000 in round numbers. On all that money they were paying an average interest of 8 per cent., which they were trying to get reduced. He referred with regret to the death of Captain Rowan, who was a notable figure in connection with electric lighting in the Australian colonies.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts for the two weeks ended March 31st were £3,358, as compared with £3,040 for the corresponding period of last year.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended March 31, 1893, after deducting 17

Hosted by Google

per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,339.

SHOOTING.—Several of the Eastern Telegraph Company's staff at Madras (general superintendent, Mr. W. T. Newitt) are members of the Madras Volunteer Guards, and distinguished themselves in the shooting competitions recently held. The following were included in the company winning the Commemoration Shield, those marked with an * taking additional prizes :—Colour-Sergeant W. Wilton,* A. J. Rebeiro,* W. C. Rebeiro, and J. W. Evers.*

INCANDESCENT LAMP MANUFACTURE.—A Works Superintendent will be shortly open to accept a POSITION in or near London. Advertiser is a Chemist by education, has had eight years expert experience, including one of the leading factories in London, also in Vienna, and is at present Superintendent of one of the largest works in the United States.—For fuller information apply to "A. S.," 2, St. Mary's-road, Canonbury, London, N.

WANTED, by an A.I.E.E., post as FOREMAN WIREMAN, or as Electrician to take charge of an installation. Good outdoor experience, having served term of pupilage with an eminent firm of electrical engineers, from whom excellent testimonials can be obtained. Locality no object.—Apply, 1225, *Electrician* Office, Salisbury-court, Fleet-street, London, E.C.

WANTED, PIVOTTING, Jewelling, Electricity Meter Trains, Cardew movements. Experimental and all kinds of fine mechanical work done.—CLARKE BROS., 32, Bravington-road, Harrow-road, W.

WIREMAN wants SITUATION; lights, bells, &c.; can run own casing.—Address, "ELECTRON," 180, Shirland-road, Paddington, London, W.

WORK REQUIRED by experienced ELECTRICAL ENGINEER.—Write "M. S.," 66, Acland-street, Limehouse, E.

J. WEEKS AND CO., Horticultural Builders to Her Majesty, H.R.H. the Prince of Wales, H.M. Government, Admiralty Dept., War Dept., Royal Hort. Soc., Royal Botanic Soc., Parks and Public Buildings. Patentees of the Duplex Upright Tubular Boilers. King's-road, Chelsea, S.W.

Miscellaneous Advertisements, Plant Wanted and for Sale, &c., &c., continued on next page,

FOR VENTILATING AND COOLING ENGINE AND DYNAMO ROOMS,

20 HIGHEST AWARDS, including PARIS, 1889.

BLACKMAN VENTILATING CO. (Ltd.), 63, FORE STREET, LONDON, E.C.

METAL SPINNING.

Having a Special Department for the Manufacture of all classes of SPUN GOODS, including—

ARC LAMP CORONAS, REFLECTORS (any Radius), SWITCH COVERS, FUSES, BOSSES, INSTRUMENT CASES, &c.,

Your esteemed inquiries are invited for Prices, &c. Any Special Goods made on the Shortest Notice. Prompt Delivery guaranteed.

THE LONDON AND LANCASHIRE ELECTRIC AND GENERAL ENGINEERING COMPANY, Limited,

Telephone: WORKS: 608. CITY: 1812. DALSTON, N.E. Telegraphic Address: "PRYKE, LONDON."

LONDON AGENCY.—Experienced ENGINEER, with large connection, having ground-floor premises with large show windows in one of the best leading thoroughfares in the West End, is open to REPRESENT a first-class firm. Highest references.—Application to be made "M," care of T. Sellers, Esq., 35, New Broad-street, E.C.

WANTED, and FOR SALE.

GAS ENGINE, 2½ horizontal (Crossley's) in good working order. May be seen at work. Price £50.—Apply by letter, WHITTON, 60, Queen Victoria-street, E.C.

J. WEEKS AND CO., King's-road, Chelsea, S.W., supply all kinds of Boilers, their improved and other Valves, tested Hot-water Pipes, Castings, Connections and Fittings at lowest retail prices.

THE ADVERTISER wishes to arrange with energetic firms who have travellers canvasing the whole of the United Kingdom for the SALE of a new first-class ELECTRIC LIGHT ARC CARBON on commission. In reply, please state what portion of the country is canvassed and what influence could be brought to bear in introducing the article named.—Address, "CARBONS," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

MESSRS. DEBENHAM, TEWSON, FARMER, and BRIDGEWATER have a large selection of SHOWROOMS, OFFICES, WAREHOUSES, and FACTORIES suitable for ELECTRICAL ENGINEERS.
Their Monthly List is now ready, and may be obtained at their Offices, 80, CHEAPSIDE, E.C., or will be forwarded free by post

ALUMINIUM SHEETS, WIRE, TUBES, or PATENT HARDENED CASTINGS for ELECTRICAL WORK.
SOLDERS (Richards' Patent) for Brazing and Soldering Aluminium. The only practical one hitherto invented.
Correspondence Invited.
W. ARCHD. BRIGGS, 87, High Street, DUNDEE.

"THE PATENTEES' HANDBOOK,"
BY
J. G. LORRAIN, M.Inst.E.E., M.Inst.M.E.,
CHARTERED PATENT AGENT,
Gives full information and advice to intending Patentees. Sent post free on application to Mr. J. G. LORRAIN, Norfolk House, Norfolk-street, Strand, London, W.C.

Messrs. WILLIAMS and NORGATE, Importers of Foreign Books, have weekly parcels from the Continent with all the new Scientific Books.
(*Foreign Prices*).

THE EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (Limited).

FIVE PER CENT. AUSTRALIAN GOVERNMENT SUBSIDY DEBENTURES

NOTICE IS HEREBY GIVEN that in pursuance of the conditions upon which the above Issue was made, the undermentioned numbers of Debentures were drawn by lot on the 6th April, 1893, at the Offices of the Company, Winchester House, 50, Old Broad Street, in the City of London, in the presence of the Assistant Secretary, and of John Venn, Esq., Notary Public.

The said Debentures will be paid off at par on 1st day of July next, at Messrs. Barclay, Bevan and Co., 54, Lombard-street, E.C., after which date interest on them will cease.

353 DEBENTURES OF £100 EACH.

JOHN VENN,
9, Gracechurch-street, E.C.,
Notary Public.

By order of the Board,
F. E. HESSE,
Secretary.

Winchester House,
50, Old Broad-street, London, E.C.,
6th April, 1893.

THE EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY, LIMITED.

NOTICE IS HEREBY GIVEN that the THIRTY-NINTH ORDINARY GENERAL MEETING of this Company will be HELD on WEDNESDAY, the 19th, day of April, 1893, at Two o'clock in the Afternoon, at WINCHESTER HOUSE, 50, OLD BROAD STREET, London, when the Report and Accounts for the half-year ended 31st December, 1892, will be submitted, a Dividend and Bonus declared, and the ordinary business of the Company transacted.

And Notice is also given that the Register of Transfers will be closed from the 12th April to the 19th April, both days inclusive.

Dated this 10th day of April, 1893.

By order of the Board,
F. E. HESSE, Secretary.

Winchester House,
50, Old Broad Street, London, E.C.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).

FIVE FER CENT. DEBENTURES (1884 ISSUE).

NOTICE is Hereby Given that, in conformity with the conditions upon which the above issue was made, the SEVENTH DRAWING for payment of these Debentures, 177 in number, WILL TAKE PLACE in the presence of a Notary Public of the City of London on MONDAY, the 17th inst., at noon, at the Offices of the Company, Winchester House, Old Broad-street, London, E.C.

By order of the Board,
RICHARD COLLETT, Secretary.

Winchester House, Old Broad-street, London, E.C.,
April 7, 1893.

SUBMARINE CABLES TRUST.

NOTICE is Hereby Given that a payment of £1. 10s. will be made on account of the Coupon due on the 15th April, on and after that date, by Messrs. GLYN, MILLS and Co., of 67, Lombard-street, London, E.C., between the hours of 10 a.m. and 2 p.m.

The Coupons should be left with the Bankers for examination Four clear days before payment. They will be stamped with the words "£1. 10s. paid." and returned to the holders.

By order of the Trustees,
A. BRODRICK, Secretary.

Winchester House,
50, Old Broad-street, E.C., April 7th, 1893.

KING'S COLLEGE, LONDON.

ELECTRICAL ENGINEERING.

A COURSE of LECTURES and LABORATORY WORK will be given on MONDAY evenings, commencing May 1st, 1893.

For particulars, apply to
J. W. CUNNINGHAM, Esq., Secretary.

INDIA RUBBER, GUTTA PERCHA AND TELEGRAPH WORKS CO.,

LIMITED.

ELECTRICAL ENGINEERS,

AND

INDIA RUBBER AND GUTTA PERCHA MANUFACTURERS.

MANUFACTURERS OF

CABLES, WIRES, INSTRUMENTS, INSULATORS, DYNAMO MACHINES, MOTORS, ARC LAMPS & FITTINGS, BATTERIES, CARBONS, TORPEDO APPARATUS.

SPECIALITY.—Underground Electric Light System for High and Low Tension. The only System which has given complete satisfaction.

Contracts entered into for the Erection and Equipment of Central Lighting Stations, the Lighting of Ships, Factories, Houses, and the Supply of Complete Plant for Electrical Traction and Transmission of Power.

VULCANISED INDIA RUBBER.

HOSE, DRIVING BANDS, STEAM PACKING, WATERPROOF GARMENTS and FABRICS, SHOE SOLES, MATS, VALVES, BRAKE BLOCKS, WHEEL TYRES for CABS, CARRIAGES, BICYCLES, &c. SHEET, WASHERS, BUFFERS, SPRINGS, TUBING, SOLID CORD, FOOTBALL BLADDERS, LAWN TENNIS BALLS. MOULDED GOODS to any Pattern.

EBONITE.

Not affected by Vinegar or Hydrochloric or Acetic Acid.

SPECIALITIES IN EBONITE FOR CHEMICAL WORKS.

INSULATORS, BATTERY CELLS, SPEAKING TUBES, SHEET & ROD, SURGICAL APPLIANCES, PHOTOGRAPHIC ARTICLES, SCREW STOPPERS, PUMPS.

GUTTA PERCHA.

TUBING, BELTING, BUCKETS, BOSSES for FLAX SPINNING, GOLF BALLS, SHEET and TISSUE.

Annual Subscription (U. K.), 19/6

NOTES.

The same week that has seen the death of one of the fathers of cable telegraphy has witnessed the successful completion of a new cable of a type never dreamed of until a few years ago. Whether the K R law on which the Irish telephone cable is based is a sure foundation or not is comparatively unimportant so long as first-rate cables are turned out. For all we know, the theory may be completely wrong. This matter will be settled some day, but it is a relief to think that, however ill-founded it may be, the speaking qualities of the London-Paris and Glasgow-Belfast cables will not be affected. Competent judges, says a Scotch paper, declare that line to be three or four times the efficiency of either of the London-Paris circuits. Unhappy word "efficiency," how many duties has it to perform! The success of this cable, particulars of which will be found elsewhere, is said to augur well for a London-Dublin line. The precise effect on the proposed Irish Parliament of easy conversation, at five or six shillings for a three-minute harangue, is happily beyond our province to consider.

The Paper by Mr. C. K. Falkenstein, which we are able, after a lapse of three weeks, to publish with the curves, is of wider interest than the somewhat unfortunate process with which it is connected. The commercial difficulties of electrical tanning companies have, however, nothing to do with the experiments and observations of Mr. Falkenstein. The distinctly different characteristics of the solid substances which were found to adhere to the electrodes in his first experiment, seem to point to a true electrolysis of the liquor. It must be remembered, however, that the hides do not form any part of the electrodes, nor are any diaphragms used in practice. The electrolysis, indeed, seems to be rather a waste of good liquor, and may, perhaps, be regarded as an accident in the process. Other experimenters have found that only about fifteen millionths of the liquor is actually electrolysed during the tanning of a batch of hides. The endosmotic effects seem to be of much more importance.

Mr. Falkenstein throws out a suggestion to the effect that the phenomenon of electricity being a vibration of the ether, chemical combinations are accelerated; but we know of no such vibrations in ordinary currents such as those employed by the author. His second suggestion is that the effect of endosmose is to propel the liquor in the direction of the lines of current flow. To examine these effects, Mr. Falkenstein has used diaphragms of porous clay and leather, and he found, and has measured, the flow of liquor through such diaphragms. While these observations are of considerable interest, it seems hardly possible to assume that a corresponding flow takes place through hides in tanning, either in the mass as in the Worms and Balé process, or when stretched as in the Groth process. In each case there is plenty of opportunity for the liquor to circulate round the hides; and although they offer but little resistance to the electric current, they must obviously behave very differently to an actual current of liquor. There seems to be an ill fate about certain problems on the borderland between chemistry and physics. The theory of solution has engaged the attention of many high authorities, but seems to become more and more involved. Electrolysis, if not settled theoretically, is, at all events, understood sufficiently well for practical purposes, and it is to be hoped that osmosis, even if as unintelligible as simple solution, may, nevertheless, become of practical importance in the commercial applications of electrical energy.

A most sensible suggestion is made in the *Builder* as to preparation in new buildings for running electric cables. In a few instances holes are left in walls and flooring by express orders, but in the large majority of cases considerable expense is incurred in cutting away work which has only been erected a few weeks before. Cutting holes is bad enough, but cutting chases is so serious that outside casing is resorted to five times out of six. Insurance companies very properly object to the running of cables in the same chase with water and gas pipes, but while these are almost invariably provided for by the builder, similar provision for electric cables is ignored. The suggestion is specially welcome, coming as it does from the leading building journal, and we warmly endorse it.

The calculations given by Mr. R. Wood in our correspondence columns are not very convincing in the absence of clearer definition of some of the terms employed. His theoretical arguments appear to depend upon a term p, representing the pounds of steam that are used non-condensing, which are saved by condensing, and these, he says, are constant for all loads on the engine. When Mr. Wood comes to actual figures taken from tables by Mr. Crompton and Prof. Kennedy, we are inclined to ask whether a simple

Hosted by Google

comparison between these tables is warranted by those who compiled them. We print his letter, as he informs us that it is *apropos* of our leading article on condensers; but so far from arriving at any conclusion, his last paragraph alludes to one or two items which leaves the whole question open. It is not seriously disputed by anyone that a condensing engine of a reasonable size is more economical than a non-condensing, and it is well understood, as Mr. Wood observes in conclusion, that each case must be decided on its merits when the local conditions were known. Where evaporative condensers are concerned, and where local circumstances will allow them to be used, the cost of water for condensing need not be considered, since it appears to be conceded that the feed-water is more than sufficient for this purpose. The Paper by the late Mr. P. W. Willans, of which an abstract will be found in another column, will throw much light on the subject of compound engines of the limited sizes employed for electric supply.

We have frequently noted with considerable surprise and no little sympathy the predominance enjoyed by German electrical apparatus in France. Had we remembered that French manufacturers, who have always "enjoyed" a large measure of protection, had recently succeeded in getting the duties on foreign goods raised all round to "compensate" them for the increased cost of home labour, we might have come to much the same conclusion as M. Ch. Haubtmann arrives at in a brief but bitter article in *L'Electricien* for April 8th. Owing to the high tariff, German electrical apparatus, as such, is not able to make much way in France, but this very fact makes it highly profitable for a French firm to purchase the French patents of some foreign electrical manufacturing concern, obtain all the patterns, &c., from the same source, and then proceed to manufacture under the shelter of the high-tariff wall. This policy certainly stimulates manufacture, but of a very delicate hothouse kind, and it utterly kills both commercial enterprise and the inventive faculty which, after all, lie at the root of permanent prosperity. M. Haubtmann points out that the great Creusot Works are sole *concessionnaires* in France of the Zipernowski-Déri-Bláthy patents, and confine themselves to a tame imitation of the plant turned out by the well-known Budapest firm of Ganz. The Société Alsacienne de Constructions Mécaniques do the same as regards Siemens and Halske, of Berlin, and La Compagnie de Fives-Lille as regards the Allgemeine Electricitäts-Gesellschaft, whilst even the Cail Works make German cables.

Guided by what it knows "respecting the laws of conduction," a contemporary connected with building and architectural matters comes to the conclusion, in a brief article on "Lightning Conductors," that "copper is the best metal for the purpose;" the natural corollary to this ancient dogma being instructions to unite pipes, lead roofs, and masses of metal generally to the discharge rod, which is "on no account to be insulated by glass rings or pitch, as is sometimes done." Not having a supply of thunderstorms on tap suitable for settling controverted points, we are unable to go bail for all that Dr. Lodge has stated in a contrary sense with regard to the theory and proper mode of erecting lightning conductors. There is, however, a sufficiency of support from electro-magnetic theory, experiment, and observed facts to render it desirable in any article likely to be read by practical men to at least mention the Lodgian theory, and to summarise the leading deductions from it. There seems to be no mean in this matter of acceptance of new scientific ideas between the "impulsive rush," which is usually accompanied by considerable distortion of the original idea, and a state of steady neglect.

Dislike the fact as we may, the fact remains that we are rapidly travelling along the "checker'd paths" leading to complete municipalisation—whether the roads run uphill or down we leave it to experts to prophesy and events to decide. The Glasgow Corporation, not content with having municipalised the water, gas and electricity supply, now contemplate applying to the Postmaster-General for a licence "to supply the community with an efficient telephone service." A municipal telephone service is an experiment worthy of a trial—north of the Tweed. Even in the far East, local authorities have caught the infection. At the last meeting of the ratepayers of the foreign settlement north of the Yang-king-pang, a resolution in favour of buying out the local electric lighting company was carried by two votes, a majority having apparently been obtained by the Yang-king-pang argument that as there was a municipal *abattoir* there ought also to be a municipal central lighting station.

Cairo.—The local Gas Company has undertaken to supply electric light.

Electricity Supply Corporation.—Mr. W. H. Patchell has been appointed chief engineer to this Corporation.

Personal.—Mr. J. W. Curra has been appointed to the technical officers' class in the Engineer-in-Chief's Office, Post-office Telegraphs.

"**Elektrotechnische Bibliographie.**"—Under this title the publishing house of J. A. Barth, of Leipzig, intend issuing a monthly list of books and articles published, dealing with electrical matters.

Electrical Engineering Course.—A course of electrical engineering lectures and laboratory work will be given at King's College on Monday evenings, commencing May 1. For particulars, apply to the secretary.

Glasgow Telephone Service.—At the last meeting of the Town Council it was remitted to a Special Committee to consider the question of applying to the Postmaster-General for a licence to supply the community with an efficient telephone service.

Royal Institution.—At the general monthly meeting of this Institution, on Monday, the special thanks of the members were returned for a £21 donation by Mr. Alexander Siemens to the fund for the promotion of experimental research at low temperatures.

Aberdeen.—At a meeting of the Gas Committee of the Town Council on Friday last, plans and specifications drawn up by Prof. Kennedy with regard to the electric lighting works were submitted. The Committee authorised the invitation of tenders for the buildings in Cotton-street.

Gas Companies and Electric Lighting.—The Manager of the Dorking Gasworks reports that he has received many representations from customers urging him to supply electricity. He therefore recommends that the Board of Trade should be approached with the view of securing its help in the revision of present arrangements.

Hosted by Google

Brighton and Rottingdean Sea-shore Electric Railway.—The Bill for incorporating a company for the construction of this line has been referred to a Committee of the House of Commons, consisting of Sir Richard Paget, Chairman, Sir J. D. Weston, the Hon. Henry Cubitt, and Mr. C. P. Huntingdon. The Committee will hold its first sitting on Tuesday next.

Mr. Henniker Heaton and the Cable Companies.—Mr. Henniker Heaton has given notice, on going into Committee of Supply, to move a resolution in favour of the acquirement by the State of the existing rights and property of the cable companies at their present market value, with the object of cheapening and facilitating electric communication with the different parts of the empire.

Southport.—The Electric Lighting Committee of the Southport Town Council, after discussing the electric lighting question for months, and having apparently made considerable progress, now find themselves, says the *Liverpool Post*, so divided in opinion as to the merits and demerits of the high-pressure alternating and continuous-current systems, that they have decided to submit the whole case to an electrical expert.

Edinburgh.—At a meeting of the Electric Lighting Committee of the Town Council held last week the question was discussed at some length whether the Corporation should themselves put in force the Electric Lighting Order, or hand it over to a company. By eight votes to three it was resolved that the Corporation should take the matter in hand themselves, and this recommendation will be reported to the next meeting of Council.

Brighton.—At the meeting of the Town Council on Thursday last week, the Town Clerk read a letter from the Local Government Board, stating that they had decided to sanction the loan of £30,000 for electric lighting purposes, on the understanding that the Council will, without delay, make a further application for authority to borrow such additional amount as may be necessary to cover the excess expenditure which has taken place.

Obituary.—We regret to report the death of Mr. Thomas H. Brayshaw, Superintendent of the Eastern Telegraph Company's system in Cyprus. Mr. Brayshaw was born in 1850, and joined the Electric and International Telegraph Company in 1863. In 1869 he was appointed to the Eastern Telegraph Company, and served in Aden, Florence, Malta, and Egypt, until 1878, when he was appointed Superintendent in Cyprus, where he remained until his death on the 11th instant, at the early age of 43.

Worcester.—Last week an inquiry was held by Major-General Crozier, inspector of the Local Government Board, with reference to applications by the Corporation for permission to borrow money in order to carry out electric lighting works and increase the filter beds at the Waterworks. The Town Clerk gave a *résumé* of the action taken by the Corporation in respect to electric lighting, and it was explained that the total expenditure contemplated under this head was £39,109, for purchase of Powick Mills, buildings, cables, &c.

Wolverhampton.—At the meeting of the Town Council, on Tuesday, Alderman W. H. Jones moved :—"That the report of the Lighting Committee relative to electric lighting be received, and that the recommendations therein contained be approved and adopted." The report empowered the Committee to advertise for a resident electrical engineer, at a salary not exceeding £300 per annum. Also to appoint an architect for the performance of such duties, fix his remuneration, and give instructions for the preparation of plans and specifications for the construction of all necessary buildings. The motion was agreed to.

A Useful Application of the Telephone.—The police authorities of Newcastle have taken a practical advantage of the telephone which might well be followed by the London County Council and other municipal bodies. They employ a combined receiver and transmitter with about 18in. of wire attached; it is very light and handy, and can easily be carried in the coat pocket. This apparatus is being chiefly used in cases of fire, when a constable, instead of breaking glass and pulling bells, has only to affix a key in the socket of the fire alarm provided for its reception; he is immediately in communication with the officer in charge of the fire station, and is able, without delay, to give full particulars.

Eastbourne.—In connection with the payment of a first dividend by the Eastbourne Electric Light Company, it is worthy of note that this Company commenced to supply electric light early in the year 1882. There are now operating 10,000 10-c.p. lamps in a circuit of nine or ten miles. There are also some 20 arc lamps running, and a contract for extending the lighting of the parade has just been entered into. The present members of the Board are those originally appointed. Mr. H. Towner, the Secretary, was also appointed at the incorporation of the Company, and has held the post ever since. Mr. H. W. Wilkinson is the present manager, and under his management the Company has made rapid strides.

Municipal Lighting in the Far East.—The municipalisation of the electric light has spread to Shanghai. At the annual meeting of ratepayers of the foreign settlement north of the Yang-king-pang, held on Tuesday, February 28th, in the Astor Hall, the following resolution was carried by 61 to 59 votes :—"That the Council be and are hereby authorised to enter into negotiations with the New Shanghai Electric Company for the purchase of the whole property, plant, and business of the Company, the Council itself undertaking the future supply of electric light for public and private use, the result of the negotiations to be laid before the ratepayers at a special meeting to be called for that purpose."

Scientific and Engineering Instruction.—We are in receipt of the prospectus of the Electrical and General Engineering College and School of Science, which is presided over by Mr. G. W. de Tunzelmann, at Penywern House, Earl's Court. The object of the College is to train engineering students in the general scientific principles underlying their proposed profession, and to prepare for the Central Institution, Cooper's Hill and the Royal School of Mines. The usual engineering course extends over two years, but there is also a special workshop course lasting a year. There are a variety of special courses, intended mainly for those actually in works who desire to study special subjects. The College is provided with physical and chemical laboratories, engine and dynamo room and workshops, and the engineering instruction is in the hands of Mr. Capito, late of Hanover-square School of Electrical Engineering.

The City Lighting.—In his report to the Commissioners of Sewers for the year 1892, Colonel Haywood states that in regard to electric lighting, there were at the beginning of the current year 409 lamps in operation, illuminating about eleven miles of streets. At the end of 1892 the Company had laid their mains and conduits in 22⅛ miles of streets. The gas lighting in the main thoroughfares was, says Colonel Haywood, discontinued from time to time as the electric lamps were put into operation. The gas lamps and fittings, however, were not removed, arrangements having been made with the gas company for cleaning and maintaining the lamps ready for lighting to meet the contingency of failure in the electric light. The number of gas lamps unlit at the end of the year was 1,126, the number of arc lamps lighted being 409; 2·75 gas lamps were extinguished for each arc lamp. The number of public ways remaining in which the Company have not laid conductors is 621, but the largest portion of these are small streets and courts and alleys.

Electric Light Wiring Facilities.—"As the majority of large buildings which are now being built, or which will be built during the next few years, will probably before long be fitted with electric light, it seems desirable," says the *Builder*, "that this probability should be taken into account in their construction. At present no one can calculate on the surprises in store for the electrical contractor. Contractors, however, would have a much clearer basis for estimate, and their rates of charges would be lower, if they could count on some preparation in the building for carrying electric cables through walls or flooring. It is too much to expect that the owner of a building which is in course of erection will put in all the necessary wiring for electric light unless there is the immediate prospect of that light being used. The cost of doing so would be considerable, and the money might lie idle for some

Hosted by Google

time. But there is little or no cost involved in arranging that at every top corner of a wall there should be two circular holes in the solid material, one connecting the two sides of the wall and the other running up to the floor above. These holes might be carefully covered over so as not to disfigure the wall, and their existence would be an immense saving in cost and labour in putting wires throughout the house at any subsequent time."

Telephone Wires in Manchester.—At the monthly meeting of the City Council on Monday Mr. Southern asked if the Paving Committee had had any application from any company for the privilege of laying telephonic or other wires underground, and whether until the Council had had an opportunity of pronouncing upon this very important question the Committee would refrain from granting any special privileges in the direction indicated. Sir John Harwood emphasised the words of Mr. Southern. He submitted that before committees gave any privileges to private parties they should take the Council into their confidence. Mr. Tunstall said that if any privileges had been allowed to those companies they had had to pay for them. There had also been a provision that the wires should be removed if the Council desired it. Mr. Alderman King said he noticed telephone wires being laid in the streets in the very place where the Corporation were about to lay their own wires. It appeared to him that there would be two jurisdictions, and if they allowed one body to lay wires there might be interference with the laying down of the electric light wires. Mr. Alderman Hinchcliffe, in reply, said that applications had been received from one or two companies for permission to lay wires underground, but that nothing would be done until a full report of the decision arrived at by the Committee was laid before the Council.

The City of London Electric Lighting Company.—At the last meeting of the Commissioners of Sewers, the Finance and Improvement Committee made a report on the subject of an application by Mr. Morse, on behalf of the City of London Electric Lighting Company, for the Commissioners' consent, as the Local Authority, to the introduction of a Bill for amending section 8 of the Electric Lighting Orders (*re* setting aside 7½ per cent. on the capital expended for depreciation). The Committee recommended, after further consideration, that the Commissioners agree that such 7½ per cent. be on the outlay for plant and machinery, &c., as defined by the Board of Trade, and that 5 per cent. on the net profits be set aside as a reserve fund, the Company, however, to be at liberty to write off as depreciation such further sum as they may think proper, or as they may be required to do by the Board of Trade, not exceeding in the whole 7½ per cent. Mr. Williamson explained that, after an interview with a Director of the Company, it was found that by mistake the word "shall" was inserted in the agreement when it meant "may." That naturally made a very great difference in an agreement of such a public character. The Company asked the Commission to allow the 7½ per cent. to apply only to the plant and machinery. It was clear that if the Company wrote off that amount on the whole of their capital it would have no chance of paying a dividend, or reducing the price of the electric light, which the Commission greatly desired. The report of the Committee was adopted.

American Electro-culture.—The cult of Thomas Alva Edison appears to have been superseded across the Atlantic by that of Nikola Tesla. A writer who hides his identity under the not inappropriate initials of J. A. M. commences "A Psychological and Scientific Study of the Man," in a technical New York contempary, with the following pronouncement:—"I can confidently state that Nikola Tesla is one of those few productions of nature that have been termed geniuses," an asseveration which is unconsciously supported by the further statement that—"Business men of to-day, and especially Americans who are thoroughly in touch with the ideas of American progress, cannot put themselves in his place." In another electrical publication we are told that Mr. Tesla "Has shown that nearly all sanitary problems can be solved by the aid of electricity;" that "he was invited to visit London and explain his experiments on the very spot made immortal by Faraday;" that he went and "manufactured flames which appeared dangerous in the extreme, and then placed them in a wooden box, which was absolutely unaffected by them." It was in London also that he demonstrated that wires and globes might be dispensed with "without impairing the efficiency of the light one fraction," though just how this was done was what "puzzled the members of the Royal Institution of London, each an expert electrician and engineer himself." After which it is a relief to learn that "Tesla does not pretend to manufacture electricity out of nothing." We could wish, also, that transatlantic technical writers would not pretend to manufacture "copy" out of nothing.

The Hopkinson Three-Wire Patent.—At a recent meeting of a Special Sub-Committee of the Glasgow Corporation, after considering the opinion of counsel on the circular letters of February 16th and 23rd, issued by the Westinghouse Company, and having regard to (1) the advantages derived from the adoption of the three-wire system, (2) the uncertain issue of any litigation, and (3) the fact that the total amount which would have to be paid by the Corporation for the use of the patent would not exceed £900, resolved that an amicable arrangement should be made with the Company for the use of their patent, upon the terms indicated in the circular letters referred to. These terms are as follows:—(1) The Corporation to pay to the Company a royalty of £2. 10s. per annum till July 27, 1896 (being the date when the patent expires), upon each ton of copper which has been, or may be, actually laid down before that date. (2) The royalty to be reckoned from the date of delivery of the copper, as shown by the invoices sent to the Corporation. (3) Accounts to be rendered on every 25th day of March, 24th day of June, 29th day of September, and 25th day of December, within 15 days of such quarter days, and payment to be made in cash within seven days from such delivery of account, in one sum, covering the period from the dates of delivery of copper detailed in the account to July 27, 1896. (4) A formal agreement, embodying the foregoing terms, to be entered into and executed by and between the Corporation and the Company. The resolution come to by the special Sub-Committee as to the arrangements to be made with the Westinghouse Company has since been approved of by the General Electric Lighting Committee of the Corporation.

The Edison Lamp Patent in America.—Our columns are, as a rule, rigidly closed to poetry, but the following effusion by "Voltabout," which recently appeared in the columns of our New York contemporary, the *Electrical Review*, has managed to pass the censor:—

To sell, or not to sell infringing lamps—
That is the question which haunts us day and night.
Whether 'tis better business tact to obey
The warnings and printed things sent out by mail—
Ay, registered mail, forsooth—
Or to take up arms against Sir Edison,
And, by opposing, get into jail? to stop—to sell
No more; and, by stopping, to find we end
The trials and the chance of paying royalty
Our trade seems heir to—'tis a consummation
We truly do not like. Ah, yes—to sell—
To sell! Perchance to gain; ay, there's the rub!
For in this trade of ours what wealth may come
When we have shuffled off this *choking coil*,
Must give us pause; there's the law's delay
That makes uncertainty of so long life;
For who can stand the costs of tedious suits,
The lawyers' fees, the proud inventor's scorn,
The pangs of despised cause, the Court's keen eye,
The arrogance of triumph, and the spurns
Acknowledged right of the unworthy takes,
When we ourselves might peaceful quiet gain
By simple acquiescence? We would contracts sign,
And trust to luck to see us through.
But that the dread of something better coming after—
From the undiscovered future which
May hold our weal—puzzles our pockets,
And makes us rather sell the lamps we have,
Than wait for others that we know not of.
These injunctions make cowards of us all,
And thus the native hue of resolution
Is sicklied o'er with the pale cast of fear.
But other lamps of great life and low price,
With this regard, may come our way
And give us chance for action.

ELECTRICITY AS A MOTIVE POWER.*

BY ALBION T. SNELL.

(Continued from page 624.)

§6. The Ratio between Radial Depth of Core and Diameter of Armature.

The following ratios between radial depth of core and diameter in gramme armatures have been taken from practice, and illustrate the difference of opinion on the subject. They all refer to bipolar machines. It will be noted that they vary from $\frac{1}{3}$ to $\frac{1}{4}$.

Table B.

Diameter of core = D.	Radial depth of core = r.
7 inches.	1·0 inch.
8 „	1·25 „
8·875 „	1·125 „
10 „	2·0 inches.
10 „	1·5 „
12 „	1·875 „
12 „	2·25 „
13 „	2·0 „
14 „	2·5 „
15 „	2·25 „
15 „	3·0 „
16·875 „	3.0 „
18 „	4·0 „
24 „	4·5 „

§7. Determination of the Number of Conductors on the Armature.

The factor neither known nor approximated to as yet is the number of conductors. This is found by putting

$$C_a = \frac{E\,60}{N_a\, n\, 10^{-8}}; \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

which determines the trial value of C_a. Dividing the necessary number of turns into the space for winding on the periphery gives the width over the insulation of one turn. Deducting the insulation thickness, say, from 7 to 8 mils on each side of the wire, the remainder gives the net width of copper. C_a may be a number that will conveniently form one or two complete layers on the armature; if such be the case a round wire may be chosen; but if the number will not fit into one or two layers, it will be advisable to use a wire of rectangular section, the width being such as to fill up compactly the winding space, and the depth such as to give a suitable air gap.

The current density has been thus far purposely neglected, as the determination of a suitable number of turns is of the first importance; and therefore special stress has been laid upon it. The relation of cross-section of copper to the current must now be carefully considered, since the heating of the armature, as well as the fall of potential ($i_a r_a$), and the efficiency of the machine depend on this. No current density can be said to be in all cases the best; it is a question of size of machine, cooling surface of armature, character of output, and time of duration of maximum load. The practical limits are between 1,500 amperes per square inch in large machines, and 3,000 with outputs as small as 5 H.P. If the number of volts to be lost over the armature resistance be determined from Table A, then r_a is known, and the cross-section of copper to give this value with the calculated number of turns can be found. It is advisable also with gramme armatures to consider the depth of copper in relation to the radial depth of armature core, since the output of the machine will vary as the depth of the copper up to a certain practical limit. This point is reached where the air gap becomes so deep that the resistance is too high for the field excitation to maintain the necessary magnetic density; or else when the circumflux,[3] $\frac{i_a C_a}{2}$, on the armature causes the length of the air gap. For with a standard size of field the excitation is practically fixed, and so a large air gap with deep back and cross fields of such magnitude that sparking ensues. It should be remarked, however, that the output of the armature is not greatly affected by even considerable differences in copper implies a weak magnetic density; and less copper means a corresponding gain in the number of lines of force.

* All rights reserved.

[3] This expression for the circumflux of an armature is applicable to machines with any number of poles, it must not be confounded with the ampere turns

Two empirical equations, due to W. B. Esson, connecting the circumflux and the armature diameter, are important; for they give at once the permissible value of C_a.

For gramme armature—

$$\text{Circumflux} = \frac{i_a C_a}{2} = D\ 1000; \quad . \quad . \quad . \quad (9)[4]$$

for drum armature—

$$\text{Circumflux} = \frac{i_a C_a}{2} = D\ 1500 \quad . \quad . \quad . \quad (10)$$

D in each case is the diameter measured in inches.

Practically, with gramme ring armatures, it is found that the best all-round results are obtained with a ratio of radial depth of copper to iron of from $\frac{1}{8}$ to $\frac{3}{16}$. With drums some 50 per cent. more copper may be allowed, as is evident from the empirical equations (1), (2), (9), and (10).

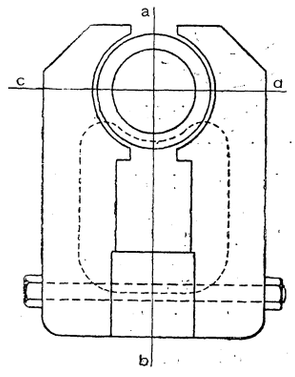

FIG. 1.—Wrought Cores, Cast Yoke, Upright Type.

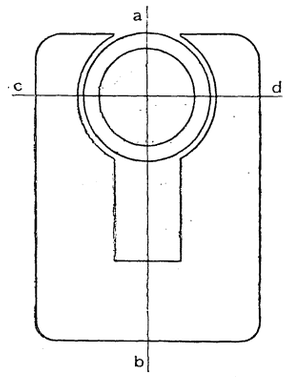

FIG. 2.—Cast Iron.

This ratio is important in gramme armatures, because the narrow section of iron must be magnetised to at least $B_a'' = 100{,}000$. In drums this ratio has no meaning, since the iron is made as deep as possible, reaching even to the shaft itself, and the depth of copper is determined simply from the heating limits and the possible length of gap, having regard to an economical field-magnet and excitation.

The thickness of the copper being known, the length of the air gap can be determined approximately. It may have to be adjusted when the field-magnet excitation is calculated from the trial equations.

§8. Design of Field-Magnets.

The function of the field-magnets is simply to supply the necessary magnetic flux with due regard to an economical distribution of iron and copper. The shape does not directly enter

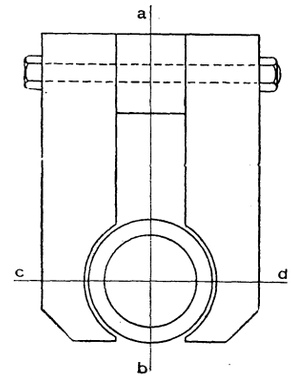

FIG. 3.—Wrought Iron Inverted Type.

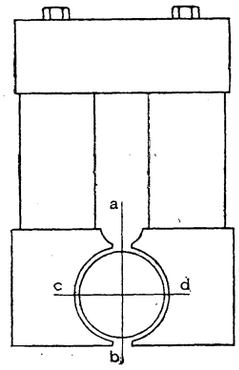

FIG. 3A.—Wrought Iron Cores and Yoke, Cast Iron Pole Pieces.

into the question, and is really a matter of convenience, and perhaps fancy. Broadly speaking, field-magnets may be divided into the bipolar and multipolar types, each of which is subdivided into a number of forms, sometimes possessing real advantages, but often only expressing individual taste. Some of the more general designs are shown in Figs. 1 to 9.

[4] In (9) and (10) the diameter is expressed in inches instead of centimetres, and so the coefficients have different values from those given by Mr. Esson.

(*a*) *The Single Magnetic Circuit Bipolar Field-Magnet.*—This popular shape of magnet is simply a development of the primitive horseshoe magnet, and is largely used in both the upright and inverted form (Figs. 1 to 3). The former arrangement has a lower leakage coefficient than the latter, and is generally adopted for small armatures; but since the centre of gravity of the rotating part is high there is a tendency to want of stability, and, consequently, with large diameter armatures the latter is more generally adopted.

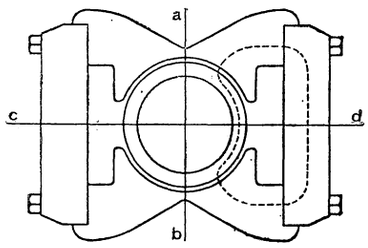

FIG. 4.—"Snell" Type of Double Magnetic Circuit Magnet. Wrought Iron Cores and Cast Iron Pole Pieces.

The single magnetic circuit field-magnet is cheap to build, and is excited with a relatively small quantity of wire. Its principal disadvantage lies in the unequal distribution of the magnet flux in the polar space, and hence inequality of induction in the armature wire. For the latter reason drum armatures are most frequently used in these fields. Large gramme rings are practically impossible with the single magnetic circuit. The largest size that is advisable is a diameter of about 12 inches; if this be exceeded there is a tendency to spark with

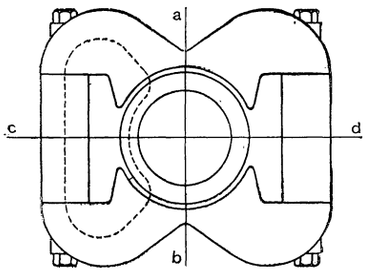

FIG. 5.—Wrought Iron Cores and Cast Iron Pole Pieces.

large outputs, so that the armature cannot be loaded to its proper limit. Larger sizes should be run in double magnetic circuit bipolar fields, or, if very large, in multipolar fields.

(*b*) *The Double Magnetic Circuit Bipolar Field-Magnet.*—Figs. 4, 5, and 6 illustrate this well-known form of field-magnet, and show the variety of ways in which it is built. The resulting distribution of magnetism is symmetrical, though the "field" as a whole may be rotated considerably. Therefore a gramme armature as large as 15 inches in diameter

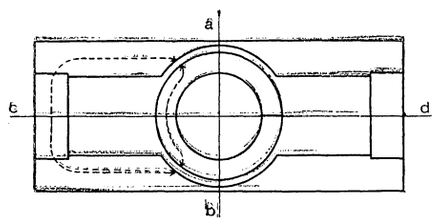

FIG. 6.—Wrought Iron.

may be profitably excited in them. The chief objection is that the number of ampere turns in the exciting coils has to be about twice as great as in the single-circuit type for a given induction in the armature. This type has also a larger coefficient of leakage than the single magnetic circuit.

If the armature be 18 inches or more in diameter, it will pay to increase the number of pairs of poles, although by doing so the exciting turns will be somewhat more numerous.

(*c*) *Multipolar Field-Magnets.*—The two types most in vogue are shown in Figs. 7 and 8. It is not easy to state exactly at what diameter of armature it is commercially profitable to depart from the bipolar type. But there seems to be some connection between the width of the polar cavity and the diameter of the armature. The ratio of interpolar space to the width of the poles, with gramme rings, is usually about 1:3; and the width of the pole, w, may be expressed in terms of the diameter, as

$$w = \frac{\pi D}{3}.$$

If the maximum economic diameter with a single magnetic circuit field be 12in. the width of pole will be $\frac{\pi}{3}\ 12 = 12{\cdot}5$ inches approximately. With a double magnetic circuit the

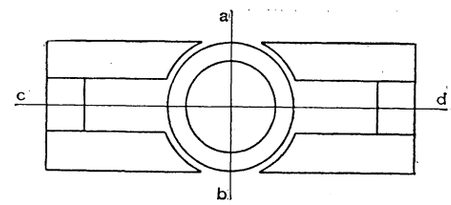

FIG. 7.—Wrought Iron. Four Poles.

diameter may be as large as, say, 15 inches; and the polar width will be $\frac{\pi}{3}\ 15 = 15{\cdot}75$. The limiting width of the polar cavities therefore varies between 12·5 and 15·75 inches. These limits accord well with practice, poles seldom being found shorter than the former or longer than the latter in multipolar designs. Continental engineers have lately developed

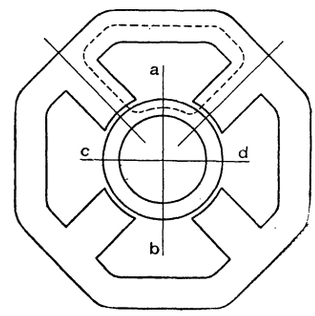

FIG. 8.—Multipolar Design in Cast Iron.

large gramme rings with multipolar field-magnets, and have attained considerable success. Recently this design has been appreciated in England and America. Some two years ago the author selected it for large transmission-of-power machines, and also for central-station dynamos; Kapp has developed the

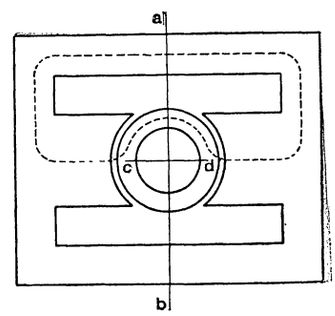

FIG. 9.—Made in Wrought or Cast Iron or with Wrought Poles and Cast Yokes. Armour-clad Type.

same idea, using, however, drum armatures; and the Thomson-Houston Company have also adopted the device for their traction dynamos.

(*d*) Armour-clad fields, as in Fig. 9, are coming into use for certain purposes, particularly for motors which have to work in very exposed positions. For tramcars, they are often built with only one exciting coil, one pole piece being made very short. This type offers no special advantages other than the excellent protection it affords to the armature and field winding.

(To be continued.)

PARALLEL DISTRIBUTION.

BY FRANCIS JEHL.

(*Concluded from page 657.*)

Let us now examine the assertion made in reference to the loop systems, and find if it is possible to always maintain a constant difference of potential between the parallels. Let us take a simple case, as given already by Kapp,* and we will use his argument. Let c_1 and c_2 be the currents taken from the line of centres, at A and B in Fig. 6, p_1 and p_2 the corresponding pressures (or difference of potential) in these points, E the difference of potential between the terminals P_1 and P_2 of

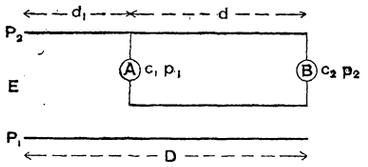

FIG. 6.

the line, and ρ the resistance of a unit length of conductor, then by applications of Ohm's law we find

$$p_1 = E - [(c_1 + c_2)\, d_1\, \rho + c_1\, d\, \rho + (c_1 + c_2)\, D\, \rho]$$
$$p_2 = E - [(c_1 + c_2)\, d_1\, \rho + c_2\, d\, \rho + (c_1 + c_2)\, D\, \rho]$$
$$p_1 - p_2 = (c_2 - c_1)\, d\, \rho \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (16)$$

If the two centres A and B were supplied at the same pressure, the difference between p_1 and p_2 must be zero, and this can only take place if $c_1 = c_2$, and in all other cases we have equation 16, and therefore the difference between the pressures in A and B cannot remain constant if the currents vary. By

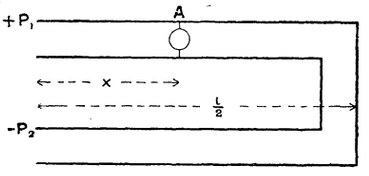

FIG. 7.

varying the difference of potential between P_1 and P_2 it is possible to keep the pressure at one of the two centres exactly at the proper standard, but then the pressure at the other centre must be wrong. It is impossible to make it right for both at the same time, and, as with a great number of centres this difficulty is not removed, but probably somewhat increased, it follows that the line of centre system does not equalise the pressure. It might be, however, objected that, by assuming only a few centres which necessarily are wide apart, we do not get a correct representation of the actual supply which will in most cases take place at a great number of points, all more or less evenly distributed. Even in that

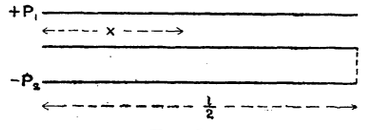

FIG. 8.

case the pressure is not equalised. To put the most favourable conditions possible, we will assume that all along the line a constant quantity of current per unit length of main is taken. Let c be the total current used in the district, l the length of the line of centres (or loop), and x the distance of A from the terminal Fig. 7. Then the current passing by A in the positive lead is $C[(l-x)/l]$, that passing by A in the negative lead is $C\,x/l$.

Let p_1 be the absolute potential in the positive lead at the distance x, and p_2 the absolute potential in the negative lead at the same distance. Then, if we call the potentials at the distance $x + dx$ respectively $p_1 + dp_1$ and $p_2 + dp_2$, we find

$$dp_1 = -C[(l-x)/l]\rho\, dx \quad . \quad . \quad . \quad . \quad (a)$$
$$dp_2 = -C\,(x/l)\,\rho\, dx \quad . \quad . \quad . \quad . \quad . \quad (b)$$

ρ being as before the resistance of a unit length of conductor. Integrating equations a and b we get

$$p_1 = -C\rho x + \tfrac{1}{2}\frac{C\rho x^2}{l} + \theta_1,$$
$$p_2 = -\frac{C\rho x^2}{2l} + \theta_2.$$

The values of the constant, θ_1 and θ_2, can be determined by putting $x = 0$ and we get $p_1 = P_1$, and for $x = l$ we get $p_2 = P_2$

$$p_1 = P_1 - \tfrac{1}{2} C\rho \left(\frac{2xl - x^2}{l}\right),$$
$$p_2 = P_2 + \tfrac{1}{2} C\rho \left(\frac{l^2 - x^2}{l}\right).$$

The difference of potential at the point A, or, as we have called it, the pressure in A, is therefore

$$p = p_1 - p_2,$$
$$p = P_1 - P_2 - \tfrac{1}{2}\frac{C\rho}{l}(2xl - 2x^2 + l^2).$$

We obtain the pressure at either terminal of the line by putting

$$x = 0 \text{ or } x = l \qquad p = P_1 - P_2 - \tfrac{1}{2} C\rho\, l,$$

If this be taken as a standard, the pressure at any distance x can be given with reference to it. It is

$$p = p_x - [(C\rho x)/l](l - x).$$

By taking the differential dp/dx and setting it zero, we get the maximum variation for $x = l/2$. Thus we get

$$p_m = p - \tfrac{1}{4} C\rho\, l,$$

which is the pressure in this point, and the greatest possible variation in pressure is $\frac{1}{4} C\rho\, l$. It will be interesting to investigate whether the single loop system offers some such advantage. We must again assume that the same amount of copper is used, but now subdivided into three mains, instead of four (Fig. 8). By virtue of this arrangement the resistance of the conductor per unit of length is only $\frac{3}{4}$ of its former value, and the length of the line (the part we are investigating) is one-half of what it was before. By making these corrections in the above formula for p, we find

$$p = P_1 - P_2 - \tfrac{3}{4}\frac{C\rho}{l}\left(xl - 2x^2 + \frac{l^2}{4}\right).$$

The greatest pressure occurs at the terminals where $x = 0$ and $x = 1/2l$; it is

$$p_x = P_1 - P_2 - \tfrac{3}{4}(C\rho\, l)/4.$$

The least pressure will be found in the middle of the line;

$$x = \tfrac{1}{4} l \text{ gives } p_m = P_1 - P_2 - \tfrac{3}{4}\, 3\, (C\rho\, l)/8.$$

Hence the greatest possible variation in pressure is $\frac{3}{4}(C\rho\, l)/8$. That is only $\frac{3}{8}$ of the variation we have found in the double line of centres (double loop) system. Let us now compare these two values of the loop systems with that of the direct system, expressing them in terms of R_d, that is, in terms of the direct system. What we have expressed as ρl in the above equations is equal to $R_m/2$, that is, $2\rho l = R_m$, and finding the values of R_m from equations 9 and 12, we get $R_m = 4 R_d$, that is, $2\rho l = 4 R_d$ or $\rho l = 2 R_d$. By substituting this value in the results found above, we get

$$\tfrac{1}{4} C\rho l = \tfrac{2}{4} C R_d = \tfrac{1}{2} C R_d \quad . \quad . \quad . \quad . \quad (17)$$

for the double loop system, and

$$\frac{3}{4}\frac{C\rho l}{8} = \frac{6}{4}\frac{C R_d}{8} = \frac{3}{16} C R_d \quad . \quad . \quad . \quad . \quad (18)$$

for the single loop system. Summing the results obtained from equations (13), (15), (17), and (18), we find that the greatest variations in pressure amount,

In the direct system ..... to $\frac{1}{2} C R_d$;
In the feeder system ..... to $\frac{13}{16} C R_d$;
In the single loop system ..... to $\frac{3}{16} C R_d$;
In the double loop system ..... to $\frac{1}{2} C R_d$.

* Kapp designates the single and double-loop, *the single and double line* of centres. *The Electrician*, Vol. XI., 1883.

Hosted by Google

From this we see that the direct and double loop systems have the same amount of variations, and that under the conditions considered, the feeder and single loop systems also vary the same.

Notice must also be taken of the fact, that in the direct system, the fall of pressure commences at the first parallel (not counting the drop on the mains leading to the first point of consumption) and ends at the last, while in the double-loop system it commences on one side at the first parallel, and ends in the middle of the line, as our equations have shown, and then rises again up to the first parallel on the other side. Thus, in regards variation, it is the same as in the direct system, but in reality there is double the drop. The same relations apply between the feeder and single-loop systems.

Let us now find the amount of energy expended in heating the mains between the first and last points of consumption, assuming that the current is taken regularly per unit of length. In the first place we will find the relative values of ρ, that is, the resistance per unit of length in each system, taking ρ_d of the direct system as unit, and expressing the others in terms of the same. The relative lengths of the four systems as already taken is 2, 3, 3, and 4. Thus

$$2\,\rho_d = R_d, \qquad (3\,\rho_f) = (R_f), \qquad 3\,\rho_l = R_l \quad . \quad (19)$$

and $4\rho_m = R_m$. Now from equations 9, 10, 11, 12 we have $R_f = R_l = \frac{9}{4} R_d$ and $R_m = 4\,R_d$, substituting these values in the equations of (19) we find that $\rho_l = \rho_f = \frac{3}{2}\rho_d$ and $\rho_m = 2\,\rho_d$.

Now, in those parts of the mains before the branches, which carry the whole current C, it is evident that the relative waste of power ($C^2 R$) is as 1 to 3/2, 3/2, 2, respectively. This, however, does not concern us, as we only wish to know the power wasted in the four different systems The supply mains, up to the different systems, can all be made of one size, thus costing the same capital and having the same loss. Let us now calculate the power wasted in the mains from branch to branch, using the formula $C^2 R$. In Fig. 9 we have a group of

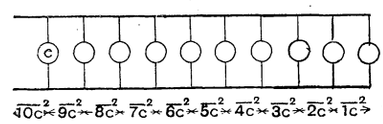

FIG. 9.

parallel branches, each branch taking a current c, and the resistance of the line or main is constant per unit of length. Now, in the first unit of length we have as power wasted $(10\,c)^2\rho$, in the second $(9\,c)^2\rho$, third $(8\,c)^2\rho$, and so on. Putting this in a series we get

$$(10\,C)^2\rho + (9\,c)^2\rho + (8\,c)^2\rho + (7\,c)^2\rho + (6\,c)^2\rho + (5\,c)^2\rho + (4\,c)^2\rho + (3\,c)^2\rho + (2\,c)^2\rho + (1c)^2\rho = C^2\rho[1^2 + 2 + {}^2 + 3^2 + \ldots + 10^2] = C^2\rho\,\frac{n(n+1)(2n+1)}{6} = 385 C^2\rho \quad . \quad . \quad . \quad . \quad . \quad . \quad (20)$$

n here is equal to the number of branches. We see that we can calculate the power wasted in any main, when that part forms part of a direct system. We may thus lay down our rule as follows: In any direct system, where the current is taken off equally per unit of length, and the resistance per unit of length of the mains being constant, we have as energy lost in the mains

$$2\,c^2\rho\left[\frac{n\,(n+1)(2\,n+1)}{6}\right] \quad . \quad . \quad . \quad (21)$$

where c is the current of each branch, ρ, the resistance per unit of length of the mains and n, the number of branches.

We must of course, as shown above, take it double, as we have two mains. Now this formula can be applied also to the other systems, plus a term, for those parts of the systems that carry the whole current. Thus if we had a district containing n number of branches evenly taken off *e.c.t.*; we would have as energy expended in the mains of the direct system,

$$2\,c^2\rho_d\left[\frac{n\,(n+1)(2\,n+1)}{6}\right] \quad . \quad . \quad . \quad (22)$$

in the feeder system,

$$4\,c^2\rho_l\left[\frac{n/2(n/2+1)(n+1)}{6}\right] + l\,\rho_l\,c^2\,n^2 \, . \quad (23)$$

Here we see that we must calculate from the points where the feeders supply, and that they supply $n/2$ on one side and $n/2$ on the other. Also the term, $l\rho_l c^2 n^2$ is the amount lost in the feeders where, l is the total length of the feeders (going and return). In the single loop system we have

$$2\,c^2\rho_l\left[\frac{n(n+1)(2\,n+1)}{6}\right] + l'\,\rho_l\,c^2\,n^2 \, . \quad (24)$$

Here $l'\rho_l c^2 n^2$ is that part of the loop carrying the whole current. In the double loop system we have

$$4\,c^2\,\rho_m\left[\left(\frac{n\,(n+1)\,(2\,n+1)}{6}\right) - 2n^2\right] \quad . \quad . \quad (25)$$

Here we have the distribution also evenly, but at double the lengths of the other systems. Now substituting the values of ρ_f, ρ_l and ρ_m in terms of ρ_d in the formulæ 23, 24, and 25, and noting that in our Figs. 2 and 3 that $l = l' = n$, we get as the relative values of the energy lost in the four systems, the general expressions in terms of the direct system.

Energy lost in direct system,

$$\frac{n\,(n+1)\,(2\,n+1)}{3} c^2\rho_d \quad . \quad . \quad . \quad . \quad . \quad (26)$$

Energy lost in feeder system,

$$\left[\frac{n}{2}\left(\frac{n}{2}+1\right)\left(n+1\right) + \frac{3}{2}n^3\right] c^2\rho_d \quad . \quad . \quad . \quad . \quad . \quad . \quad (27)$$

Energy lost in single loop systems,

$$\frac{3}{2}\left[\frac{n\,(n+1)\,(2\,n+1)}{3} + n^3\right] c^2\rho_d \quad . \quad . \quad (28)$$

Energy lost in double loop system,

$$\left[\frac{4\,n\,(n+1)\,(2\,n+1)}{3} - 2\,n^2\right] c^2\,\rho_d \quad . \quad . \quad (29)$$

n should always be an even number, and greater than 2 in order to make fair comparisons with the four elementary systems. By putting n equal successively 4, 6, 8, 10, and assuming $\rho_d =$ unity and $c =$ unity we get the following values as energy lost in the four systems.

n =	Direct system.	Feeder system.	Single loop system.	Double loop system.
4	60	126	186	208
6	182	408	597	656
8	408	948	1,380	1,504
10	770	1,830	2,655	2,880

From this we see that the waste of energy is the least in the direct system, and the greatest in the double loop system,

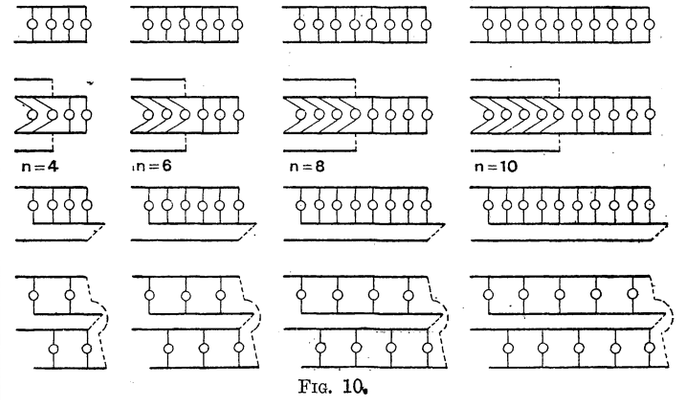

FIG. 10.

Also that in the feeder it is less than in the single loop. We must also notice that the waste of power in the direct system is all in the mains from which the branches emanate, while in the feeder system, there is only a small amount wasted in the secondary mains, the principal amount being lost in the feeders. In the single loop system part is lost in the mains which have branches, and part in the main which carries the whole current, while in the double loop the whole is wasted in the mains from which the branches spring or issue. The formulæ given above can be easily verified, by calculating from unit length to unit length the power wasted in the mains, as per example, if we calculate from Fig. 10 the power

Hosted by Google

wasted, when $n=4$, 6, 8, 10 we will arrive at the same figures as given above. We must remember that the same amount of copper is used in the four systems, and that their relative length is 2, 3, 3, and 4, and consequently the unit resistances per unit of length, taking that of the direct system as unit are $\rho_d=1$ for the direct, $\rho_f=\rho_l=\frac{3}{2}\rho_d$ for feeder and loop, and $\rho_m={}^2\rho_d$ for the double loop.

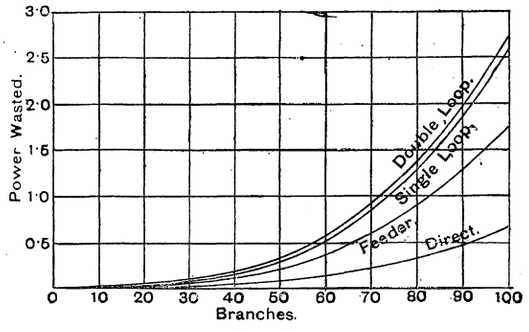

FIG. 11.

From the formulæ 26, 27, 28, and 29 we can construct the curves as shown in Fig. 11, which show us the *relative power* wasted in the different systems under consideration with a given number of branches.

NORTHRUP'S NEW DRY CELLS.

BY J. T. SPRAGUE.

Primary batteries are becoming of secondary importance as their place is taken by the dynamo, and by supply from main services. Secondary batteries will further displace them as commercial enterprise provides facilities for charging them; but they have still their uses, and will always fulfil some special purposes, notwithstanding the cost of the energy they supply as compared with other sources. They are like watches and clocks, which are not likely to go out of use, although from the point of view of foot-pounds utilised they are very costly pieces of machinery. For the special residuary uses of primary batteries the so-called "dry cells" appear to have advantages, and a compact form giving high E.M.F. is described in a Paper read to the Franklin Institute in March last by Mr. E. F. Northrup.

The author recites the general principles which govern primary batteries, and the steps which led to the construction which he has devised. He says that all substances may be divided into (1) non-conductors: (2) conductors not decomposed by electric current; (3) electrolytes or conductors which are so decomposed, and shows that while class 1 is out of consideration, class 2 cannot maintain a current except by means of an outside energy or E.M.F. Again, substances of class 3, while they can transmit current and energy, can only produce them when a differential stress is produced between the two electrodes, such stress being in fact proportional to the difference of the chemical affinities at work. Hence the conditions of a good battery are:—(1) The electrolyte capable of decomposition; (2) two electrodes differing as much as possible in potential; (3) a depolariser or agent, chemical or mechanical, which removes the ions and prevents the establishment of electric equilibrium in the liquids; all being of good conductivity.

The *positive* electrode is almost necessarily zinc, from considerations of cost and efficiency.

Negative electrodes are:—(1) Those which have to be depolarised by a chemical agent not united to it; (2) those which unite with a freed ion; (3) those which depolarise themselves mechanically, or, as in the single case of arsenic, by a chemical union. Mr. Northrup states that a couple,

$$Zn \mid H_2 S O_4 \mid As,$$

employs very cheap materials, but only gives volt 0·7, and many other objections prevent its being of practical use; but he does not mention, for the benefit of experimenters, the most fatal objection, viz., that it sets free a most deadly gas, arseniuretted hydrogen. It is remarked that where a metal is reduced it should be of the same potential as the electrode to prevent local action; thus, "with copper oxide as depolariser, copper, and not carbon, should be used." Yet carbon negatives have been used with copper salts for this very reason, that copper will be deposited while current passes, and then slowly redissolved when the circuit is open. But when the product is inert, as $Pb\ O_2$ reduced to Pb O or $Pb_2\ O_3$, carbon makes the best electrode, and may, "as we shall see later, be made to serve the purpose of a porous cup, as well as electrode." This, however has long been known and utilised in several forms of battery—Faure's bottle, Bunsen, and others.

Electrolytes available in cells are substances containing one or more of the six elements, S, O, Fl, Cl, Br, and I; of these fluorine is not practically useful, owing to the volatility and acrid nature of its products. Acid and alkaline electrolytes give higher E.M.F. than salts, but act upon the positive electrode, the zinc, and, as a rule, these are best suited to open cells giving large currents, while neutral salts are best for closed cells giving small and occasional currents.

The author makes a judicious observation as to selection of electrolytes. He says that the salt containing the metal of the positive electrode and the acid radical of the active depolariser is the best, because that salt is formed by the action of the cell, and if other salts are present there is liability to secondary actions; this is, in fact, the trouble of the Leclanché cell. Thus, he says, in a zinc carbon cell with bromine as depolariser, zinc bromide is a better electrolyte than magnesium chloride. Next to this the best selection is a salt having the nearest similar relations of E.M.F., &c.

The *depolariser* must be a substance which will readily take up hydrogen, as this is the real polarising agent, and practically O, Cl, Br, or I must be used in some available condition, there being difficulties in the use of them in the free state, as all of them act on the positive electrode, and it is impossible to maintain a separation for any lengthened period, either by porous diaphragms or gelatinous mixtures as used in the so called "dry cells." Oxygen and chlorine, being gases, are useless for these small cells, while bromine and iodine are non-conductors; Br is also a highly diffusible liquid, while I, though nearly insoluble in water, is soluble in iodides of the metals. The methods employed by the author are—(1) to give the depolariser the form of a substance insoluble in the electrolyte, except when current sets up a change in the conditions; (2) to use a heavy, oily liquid having no tendency to diffuse from the bottom of the cell.

$Pb\ O_2$, $Mn\ O_2$, and other solids used, do not act perfectly, because they do not liquify, and they cause high resistance. Silver chloride and copper oxide have advantages because the process of reduction diminishes resistance by forming a porous metallic mass. Bromine is a cheap and powerful agent,

$$Zn \mid Mg\ Cl_2 \mid Br \mid C,$$

giving 1·9 volts; it is easy to handle, and when dissolved in $C\ S_2$ loses largely its fuming nature. Mr. Northrup used this in a porous electrode made of a piece of arc-light carbon, $\frac{1}{2}$in. diameter, and 2in. inches long, in which a 3-16th hole was drilled, packed with grains of carbon, filled with bromine, and stopped with a carbon plug, connected with a platinum wire, and placed with a sheet of zinc in a 5oz. beaker containing a solution of caustic potash. This gave over 2 volts and a current of 3·25 amperes on a low external resistance, though, of course, only for a short time, as the bromine was soon used up.

"Any cell which uses as its depolariser a salt with a haloid acid radical should make use of some such substances as Mg O or Zn O if gassing is to be prevented," as pastes of starchy matters, or hydrate of silica, do not neutralise acids. The *sealing* of the cell is also important, in view of its preservation, and that used in the cell described consists of—(1) A film of cork placed over the paste to hold the zinc in position; on this is poured a layer of a hot mixture of gutta-percha, pitch, and resin oil. This is again covered by a layer of the same mixture with an equal part of plaster of paris added to it. The

Hosted by Google

actual cell described is shown (Fig. 1) to half scale. It consists of a glass specimen tube: A is the carbon electrode with platinum connecting wire, D, moulded into it; G is the depolariser; B the zinc surrounded with C, a paste of aluminium hydrate and zinc chloride with a little manganese dioxide, used partly to thicken the paste and partly to improve its appearance; E and F are the two layers of the seal. Fig. 2 shows a form of carbon electrode used in larger cells, and for still larger cells a grating of porous carbon is used, in which the solid depolariser is packed just as the lead peroxide is held in the lead gratings for secondary batteries.

It is stated that the resistance of these small cells is at first 25 or 30 ohms, falling somewhat in action. The E.M.F. with sulphur iodide is 1·45 volt, and the total output 0·2 to 0·3 of an ampere hour. But the author adds in a note that later experiments show "that Hg O, one part ground up with four parts I, with a little alcohol, makes the most efficient and durable depolariser he has yet tried."

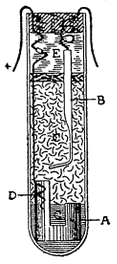

FIG. 1.

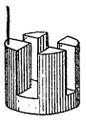

FIG. 2.

A series of the working curves of such cells is given, and compared with those of silver chloride and copper oxide cells. These show that the cells are very fairly constant, a slight fall of E.M.F. and also of R in the first few minutes resulting in a current line which is nearly straight after the first small drop. Such small cells are, of course, suited only for special purposes, such as testing, and Mr. Northrup remarks: "Assuming the average resistance is 1,000 ohms, that 40 volts are used, and the duration of each closure is one second, 17,500 taps would be required to exhaust one of the smallest cells, and 57,375 to exhaust one of the larger ones." The larger cells, similar to Fig. 1, with a cubic capacity of 1·1 cubic inch, with Hg O + I as depolariser, gives 1·4 voltage and 0·64 ampere hour total output.

THERMAL GALVANOMETERS.

BY E. TREMLETT CARTER.

In *The Electrician*, Vol. XXIX., page 589, an ingenious hot-strip ammeter, the invention of Captain Holden, was described. This description led the writer to criticise the action which goes on in such electrical measuring instruments, and to inquire into the cause of the force, and the source of the energy, which moves the pointer to the proper deflection. For this inquiry the reader is referred to Vol. XXX., page 249; and in the same number of *The Electrician* the Editor proposed the following interesting problem, which bears directly on the subject:—"A simple experiment might be arranged by taking two long wires, similar in every respect, and hanging, say, a pound weight to one of them, and an ounce to the other. Pass the same current through the two, heating them and causing them to extend. Now cut off the current, and one wire in retracting would appear to do more work than the other. . . Will these two wires assume the same temperature? By how much is the resistance, and therefore the C^2R, affected by the difference in tensions? As the pound does work in falling, will this appear as heat in the wire? And finally, does one wire really do more work than the other?" The writer purposes now to attempt to answer these questions, and to investigate further the principle of the action of thermal galvanometers.

The answer to the first question depends on that to the second; for the limiting temperature of each wire is attained when the rate of diffusion of heat from its extended surface is equal to the rate of dissipation of electrical energy in overcoming the resistance. In this matter we are considerably helped along by the recent researches of Messrs. Gray and Henderson, on "The Effects of Mechanical Stress on the Electrical Resistance of Metals," a paper on which was communicated to the Royal Society by Lord Kelvin. The conclusions arrived at by these experimenters is that "for practical purposes any mechanical treatment, however severe, does not affect the electrical properties of the metal tested." To be more exact, they have found that the maximum permanent stretching of copper produced a permanent alteration in specific resistance of only 1 per cent.; and in the case of steel, a temporary alteration of specific resistance equal to 1·6 per cent. was produced by stretching within the elastic limit. We may assume, then, that difference in loading does not cause any serious difference in the *specific* resistance of the two wires.

Applying Young's modulus, to obtain the amount of increment in length and decrement in diameter of the wires, we should find that the actual resistance of the wire carrying the pound would be slightly higher to start with than of that carrying the ounce, so that the former would continuously dissipate more energy per second than the latter. At the same time, it must be remembered that the change in length under such a stress—if well within the elastic limit—would be very small, that the alteration of section would be even smaller, and that there would be a slight increase in the surface of the wire tending to increase the diffusion of heat. If we assume that the coefficient of radiation remains unaltered—which it probably would do—there would arise in each wire, as the stretching force was applied, a small increase in its resistance, causing C^2R to become greater, and an opposing small increase in its radiating surface, which would tend to equalise the temperature. The exact relation between these two conflicting tendencies will depend on the material of the wires. Poisson's ratio has been investigated for some metals by the above-named experimenters, who have found that in the case of copper the alteration of density is only one-half per cent., and in lead only four-fifth per cent. According to Unwin, the value of Young's modulus for copper is 36,000,000lb. per square inch, and the elastic limit of this material is, when under tensile stress, 4,300lb. per square inch. Suppose the wires to be each one metre long and one millimetre in diameter, then the equal resistances will be 0·206 ohm. Now, put a pound weight on one and an ounce on the other. The first becomes 100·02228cms. and the second 100·00141cms. long; and, neglecting the change in volume—which would be of a still lower order—their resistances would immediately increase proportionately to the squares of their new lengths. If one ampere be sent though each wire, there will be 0·2060915 watt wasted in the former and 0·2060590 wasted in the latter. Now, their surfaces, before heating takes place, are 31·4194 sq. cms. and 31·4181 sq. cms. respectively. So that the former and more heavily loaded will rise to that temperature at which it will radiate 0·00655937 watt per cms. continuously and the latter to a temperature at which the radiation per sq. cm. will become 0·00655859 watt. Taking a coefficient of radiation equal to 0·0105 watt per cm. 1°C., the limiting temperatures will be 0·62470°C. and 0·62463°C. respectively, above the temperature of surrounding objects; or, in other words, the more heavily loaded of the two wires will rise to a limiting temperature 0·0112 per cent. higher than the one bearing the lesser load. A still further correction becomes necessary when we consider the *final* lengths of the wires; for the unequal expansion causes an unequal increment of their initial resistances. It is not necessary, however, to investigate this effect, for it will manifestly tend to increase the difference between the limiting temperatures.

We now come to question three. The writer thinks there can be little doubt that the energy expended by the weight in falling takes the form of heat. This conclusion is strengthened by the fact that if a live load is applied to a chain or a vertical wire, as in the experiment under consideration, the temperature is temporarily raised, the rise being due to the deformation which momentarily takes place. On the other hand, it cannot be supposed that this heat causes and maintains the

Hosted by Google

difference in temperature in the wires; for it is only momentarily, and not continuously, generated. What happens when the current is switched on is this: heat is generated internally on account of the resistance, and heat is simultaneously generated on account of the fall in the level of the weight. The sum of these two amounts of heat must at any instant be equal to the sum of the radiation from the entire surface of the wire and of the heat which is being stored; or, in other words, the total rate of heat production from every cause must equal the rate of radiation *plus* the rate of storage of heat by rise in temperature. The effect of increasing the weight on the wire is, then, to cause the limiting temperature to be arrived at earlier—to increase the steepness of the curve representing the temperature rise. *At* the limiting temperature all the heat is generated by the current alone. It will be seen that the effect is analogous to that which causes the difference between the true and the spurious specfic heats of gases.

When the current is switched off, the wires lift their respective weights to the initial levels, and thus do work against gravitational attraction. Of the reality of this work there can be no dispute; the question is as to its source. That a pound or an ounce weight lifted a certain fraction of an inch represents the same amount of work, whether lifted by hand or by the contraction of a wire, necessarily follows from the impossibility of affecting either mass or the value of g by any known physical process. The question is, whether the energy which does this work is due to the current or not. The probable explanation is that the rate of cooling of the wire is assisted by the load, just as the rate of heating was assisted. The whole subject is enveloped in the mystery which surrounds the physical explanation of the elasticity of solids—a mystery which has not yet been penetrated by the keenest mathematical mind of the present day; but some help may be derived from a consideration of the case of gases. When a gas under pressure contracts, on account of diffusion of heat through the walls of the containing vessel, its rate of cooling is *less* than if the same gas were allowed to cool without contraction, the reason being that work is done by the external pressure, which work is turned into heat in the gas. Now a gas cannot be put under negative pressure (tension), but a wire is an elastic body which can; and there seems no reason why the effect of negative pressure on the latter should not be the *reverse* of the effect of positive pressure on the former. Allowing that this may be the case, we find that the probable effect of putting a cooling wire under tension is to accelerate its rate of contraction. The source of energy to enable the wire to lift the weight would, in that case, be the heat in the metal. Some of the heat would be dissipated, but less than if the wire were not under tensile stress.

We may illustrate this further by considering what would take place if a pound and an ounce were held in suspension by hot wires of equal lengths, not at slightly different temperatures, but at absolutely the same temperature. Then both wires would have the same amount of heat energy in them; yet one would do more work than the other, because it would lift the greater weight to the same—or practically the same—height. What is the explanation of this apparent paradox? If we apply our theory of accelerated rate of cooling, as above, we find that a large proportion of the heat of the less loaded wire escapes by radiation, and only a small amount of it does lifting work; whereas, with the more heavily-loaded of the two wires, cooling occurs more quickly, there is less time for the heat to radiate away, *less heat will radiate away*, so that more heat will be available to do lifting work—namely, sixteen times as much heat as in the other wire. The total heat is the same in each case, and might be due to the same current flowing through quite the same resistance; but the distribution of that heat into lifting work and radiation is different for different loads. Such are the conclusions which have been forced on the writer by applying the method of analogy. We are unacquainted with any adequate theory of the elasticity of solids; but the elasticity of gases has long been discussed to a satisfactory solution, and this, together with other well-established physical laws, would seem to point to the conclusion we have drawn as being the only admissible one.

STEAM ENGINE TRIALS.*

BY THE LATE P. W. WILLANS, M.INST.C.E.

The Paper dealt with an extensive series of condensing trials made with a 40 I.H.P. Willans Central-Valve Engine. These were intended to form a sequel to the investigations described in the Author's Papers, entitled, "Economy Trials of a Non-condensing Steam-Engine, Simple, Compound, and Triple," read before the Institution in 1888 and 1889. The principal objects in undertaking these trials were—(1) To ascertain the initial condensation in the first cylinder, and to trace the behaviour of the steam in the succeeding cylinders, when working as a compound or triple-expansion engine; (2) To observe the effect of speed of rotation, area of exposed surface, and range of temperature, upon the initial condensation, and upon economy generally; (3) To ascertain the percentage of the theoretical mean pressure actually obtained; (4) To ascertain the ratio of the work done by each pound of steam to the theoretical work due from it; (5) To determine the consumption of steam at all loads, and under various conditions.

The consumption of steam was determined by discharging the condensed water from the exhaust into a tank carried by a weigh-bridge and observing the intervals of time required for fixed weights of water to run in. By this method, a continual watch was kept on the performance of the engine during the whole trial, and any disturbing cause was immediately detected; leaky steam-pipe joints did not affect the result, and the length of the trial might be much reduced. Special experiments, made to ascertain whether any addition was necessary to cover leakage in the engine and exhaust-pipe, showed that this leakage was slight.

The method of determining the theoretical work due from one pound of saturated steam when discharging into a condenser was next considered, and it was shown that the thermal efficiency of a condensing engine must of necessity be less than that of a non-condensing engine, owing to the greater proportionate size of the "toe" of the diagram cut off for practical reasons. In the non-condensing trials the best number of expansions was computed from the approximate formula $p^6 v^7 =$ constant; but for the condensing trials the error in this could not be neglected. The best ratio of expansion and mean pressure were therefore calculated for adiabatic expansion by Mr. MacFarlane Gray's $\theta\phi$ diagram, combined with a volume curve. Altogether, 62 trials were made under various conditions of speed, steam-pressure, load, and ratio of expansion, as well as with the engine working simple, compound, and triple, and the results were embodied in the tables accompanying the Paper.

One of the principal deductions from these experiments was the "straight-line" law of steam-consumption; and it was shown by diagrams that the *total* water for the horse-power corresponding to any mean pressure P, was W+K P, where W was the water which would be used by the engine at zero mean pressure (through initial condensation, radiation and conduction), supposing it were frictionless, and K was the water per hour required to produce each pound of mean pressure. These factors were shown to vary with the conditions under which the engine was working.

Eighteen of the trials were planned to assist in determining the law connecting initial condensation with revolutions; and it was found that in the high-pressure cylinder at high mean pressures the total condensation per unit of time was directly proportional to the square root of the number of revolutions per unit of time. As the mean pressure was diminished, the condensation became more and more nearly constant at all speeds; and finally, at low mean pressures, the law appeared to be reversed. For the low-pressure cylinder the law was modified.

The important question of the changing proportions of steam and water present during the expansive part of the stroke was investigated by the $\theta\phi$ diagram. The matter was first examined theoretically by considering the effect of a thin liner of infinitely-conducting matter, and a curve was drawn on the $\theta\phi$ diagram showing the rate at which the steam initially condensed in warming up the liner from the exhaust to the initial temperature was re-evaporated as the expansion proceeded. The actual re-evaporation, as obtained by measurement of the indicator cards, was compared with this theoretical re-evaporation, the difference measuring the delay in the return of the heat from the liner to the steam. The losses due to conduction and radiation, to passage through ports, and to incomplete expansion, could also be shown on the $\theta\phi$ diagram.

The question of the economical advantage of reducing the power by automatic cut-off *versus* throttling was discussed. Broadly, the result was that the gain by varying the expansion was large for a simple engine, moderate for a compound engine, and for a triple engine almost inappreciable. It further appeared that the gain at high speeds was greater than at low speeds. A few trials made

* Abstract of a Paper read before the Institution of Civil Engineers on April 11th.

Hosted by Google

with the cylinders steam-jacketed showed a slight gain, but further experiments were required to show whether the gain was likely to be worth the extra trouble and expense involved. The missing steam at cut-off varied in the trials to even a greater extent than it did in the non-condensing trials—the amount being much affected by the range of temperature, the density of the steam, and by other conditions.

It appeared, that, under all circumstances, the triple-condensing engine showed an advantage over the compound in regard to steam consumption; but that, except for very large engines, the compound-transfer engine was probably the best for pressures below 150lb. (absolute) pressure per square inch.

THE DETERMINATION OF HIGH POTENTIAL DIFFERENCES.*

BY DR. A. HEYDWEILLER.

The author remarks that Thomson and Tesla have given their potential differences as being as much as half a million volts, but points out that this is only an estimate. The highest pressures actually measured up to date are probably not over 50,000 volts. The easiest method is, of course, the measurement of sparking distance, which gives with periodic electromotive forces the maximum and not the effective volts; but the method assumes the discharge potentials for every kind of length of gap, and the author points out that all formulæ hitherto published tend to give infinite voltages with growing length of gap, and this is only true when the electrodes are two infinite parallel planes. The electrodes usually employed are two balls. Kirchhoff has given equations for this case to determine the rate of fall of potential at the place of discharge from known values of radius of balls, sparking distance and potential. Table I. is calculated from these equations and gives values of rate of fall of potential g_1 and g_2 for an insulated and earthed electrode; v is the discharge potential, d the sparking distance, and r the radius of the balls.

Table I.

d/r	$g_1(r/v)$	$g_2(r/v)$	$(g_1+g_2)\,r/2\,v = g\,r/v$	d/r	$g_1(r/v)$	$g_2(r/v)$	$(g_1+g_2)\,r/2\,v = g\,r/v$

The author has already shown† that the arithmetical mean

$$g = \tfrac{1}{2}(g_1 + g_2)$$

(called for short the "mean" rate of fall of potential in discharge) is independent of the distance apart when this is not too small. It is possible, therefore, knowing the value of g which depends on r, to determine from Table I. the discharge potential difference for any sparking distance. In experiments on this point note that the rate of fall of potential g is dependent on the density of the air; being diminished about 1% for every diminution of 8mm. in the height of the barometer or 3°C rise of the thermometer. The electrodes must not be influenced by neighbouring bodies. Note that the law leads to $r_{max.} = 2gr$ for infinite distance apart, and does not give an infinite value.

Using a torsion-balance mirror electrometer (see Figs. 1 and 2), the author made extensive experiments on the above law, the results of which are summarised in Table II.

* Abstract from the *Elektrotechnische Zeitschrift*.

2·0	61	6·0	147
2·5	75	7·0	162
3·0	87	8·0	175

All this applies to slowly raised pressure. The author had made no experiments on rapidly altering potentials.

Rope-Gearing.—The experiences of a French engineer have convinced him that the cost of maintaining rope gearing is three times that of belts. The weight of the ropes, moreover, is 2·64 times that of belts, while the loss in transmission is 5·77 per cent. with ropes and only 1·44 per cent with belting.

THE COATING OF CYLINDER WALLS.*

BY A. BANDSEPT.

The process of lining, not the outside as is usually done, but the interior walls of a cylinder which come into direct contact with the live steam, with a non-conducting coating is deemed by Prof. Thurston to be "the final and last improvement" of the steam engine. Iron, as ordinarily employed, is very avid of heat and quickly conducts it to the open air to dissipate it by radiation. To remedy this defect it is necessary to suppress, or rather mitigate as much as possible, condensation during admission. To attain this end we must employ for cylinder walls a metal having a low specific heat, or as it would be difficult to dethrone cast iron, we must coat this all over the surface in contact with the steam with a superficial non-conducting layer having some chance of lasting. Prof. Thurston pointed to the method described by M. Dwelshauvers-Déry in the *Révue des Sciences pures et appliquées* of February last, and which may be succinctly summed up as follows:—The substances to be coated are submitted for several days to the attacks of dilute nitric acid. A spongy material is obtained in this way which lends itself to impregnation with a non-conducting varnish. Linseed oil is then spread over the surface and adheres to it, filling the pores of the metal. Experiments on a small scale show that this process results in a considerable saving. Prof. Thurston, however, recognised that this glazing process was very far from an ideal one, and, therefore, emphasised the importance of giving the problem a more complete solution.

I think I can point out another way, of which I have had some experience, by which we can attain the desired result. The process consists in incorporating with metallic surfaces, previously expanded by heat, refractory non-conducting finely divided substances, projected with force by means of a pulveriser actuated by steam under pressure. These substances, brought to a state of extreme tenuity, are carried on to the body to be penetrated in the form of a fog, while the metal is cooling and its pores contracting. The non-conducting material lodges in the atomic interstices of the surface to be treated, so that in addition to the mechanical action, which is made use of to apply the glaze, there are intimate reactions between the smallest elements of the bodies in contact. The penetration thus becomes complete, and by passing the surface so treated under the roller, the non-conducting substances are spread evenly over the uppermost layers of metal, of which they become an integral part. In order to insure success it is sufficient that the active layer, some few tenths of a millimetre in depth, should be brought to a temperature sensibly h gher than the maximum at which the engine works. The non-conducting substances are projected in a gaseous state by steam pressure, and by means of a spiral or centrifugal jet. The lubrication of the contact with the piston is easily attained by polishing the treated surface at a high speed.

A simple and practical method of preparing steam cylinders for the molecular incorporation of refractory non-conducting substances in a state of powder is to plunge the surfaces whose conductivity we wish to destroy into an electrolytic bath. Under these circumstances, and with a suitable bath, the metal becomes the seat of reactions caused by the passage of the current. As in other cases the current spreads over the surface of the conductors in the manner which I claim to have demonstrated in my memoir "On the Propagation of the Electric Current," and if care is taken only to dip the cylinder very slightly into the liquid, the molecular disturbances not being able to diffuse themselves over the bath, will be confined to the metallic surface which constitutes the focus of the reactions. Exposed in this way the surface will be brought to a very high temperature, and will become susceptible of being reduced by the pulverising process just described. In order to avoid the use of powerful currents, the surface to be treated can be divided up. The electrolytic solution can be placed in a narrow trough approximately the same length as that of the cylinder. This trough is placed against the internal wall of the cylinder in such a way that the liquid only moistens a narrow strip of metal, the length of the cylinder. By giving the cylinder a slow rotary motion round its axis, longitudinal strips —elements of the internal surface—come successively into contact with the liquid of the trough, into which they dip slightly. When the current is switched on, the strip of metal becomes red hot. On either side of the trough nozzles are placed, which project the powdered substances on to the red hot metal as it emerges from the bath. During electrolysis the uppermost atomic layers alone take part in the transfer of the current, the underlying layers are not directly affected by the disturbances, of which the internal surface of the cylinder is the seat. The heat, therefore, has not time to penetrate far into the metal before the latter is impregnated and penetrated with the finely-powdered non-conducting substances. The superficial treatment to which the walls of the cylinder is subjected has but an insignificant effect on its outline. The walls can be surfaced before treatment, and have only to be polished up afterwards.

Mechanical pulverisation, owing to the effect which it has on the physical and chemical properties of bodies, presents a vast field of investigation in connection with improvements in certain branches of the industry. Substances in a state of extreme tenuity often give results which would otherwise be unattainable. The reactions between the minute elements in contact are rendered more easy and more thorough, and the multiplication of surfaces tends to the production of phenomena which are not manifest when masses alone are concerned, and in which action is confined to surfaces in imperfect contact. The process in question relates to a subject of the highest interest, one with which specialists are much occupied at the present moment; finally, it is only a particular application of the method of impregnating by pulverisation described in the *Bulletin* in 1887.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, April 14th.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. Paper to be read: "The Manufacture and Efficiency of Armour-Plates," by D. Carnegie, Stud.Inst.C.E.

ROYAL INSTITUTION.

9 p.m. Evening Discourse. "Seals," by Sir W. H. Flower, F.R.S.

SATURDAY, April 15th.

ROYAL INSTITUTION.

3 p.m. Tyndall Lecture: (1) Some Applications of Electricity to Chemistry," by James Swinburne, M.Inst.E.E.

TUESDAY, April 18th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be discussed: "Steam-Engine Trials," by the late P. W. Willans, M.Inst.C.E., after which there will be the monthly reception by the President and Council.

WEDNESDAY, April 19th.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Ordinary Meeting. Papers to be read: (1) "The Direction of the Wind over the British Isles, 1876-80," by F. Campbell Bayard, L.L.M.; (2) "Notes on Photographs of Lightning taken at Sydney Observatory, December 7, 1892," by H. C. Russell, F.R.S.; (3) "Notes on Lightning Discharges in the neighbourhood of Bristol, 1892," by Ernest H. Cook, D.Sc.; (4) "Constructive Errors in some Hygrometers," by W. W. Midgley, F.R.Met.Soc.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Some Economic Points in connection with Electricity Supply," by Gisbert Kapp.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Ordinary Meeting at 20, Hanover-square, W.

THURSDAY, April 20th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Atmosphere," by Prof. Dewar, F.R.S.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Ordinary General Meeting at the Institution of Civil Engineers. Papers to be read and discussed, as far as time permits: (1) "Second Report to the Alloys Research Committee," by Prof. W. C. Roberts-Austen, F.R.S.; (2) "Tensile Tests and Chemical Analyses of Copper Plates from Fire-Boxes of Locomotives on the Great Western Railway," by William Dean; (3) "Research Committee on Marine-Engine Trials; Abstracts of Results of Experiments on Six Steamers, and Conclusions drawn therefrom in regard to the Efficiency of Marine Boilers and Engines," by Prof. T. Hudson Beare, F.R.S.E.

CHEMICAL SOCIETY.

8 p.m. Ordinary Meeting.

FRIDAY, April 21th.

INSTITUTION OF MECHANICAL ENGINEERS.

7.30 p.m. Ordinary General Meeting.

OLD STUDENTS' ASSOCIATION.

8 p.m. Smoking Concert at Masons' Hall Tavern.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Possible and Impossible Economies in the Utilisation of Energy," by Prof. A. B. W. Kennedy, F.R.S.

SATURDAY, April 22nd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Some Applications of Chemistry to Electricity," by James Swinburne, M.Inst.E.E.

PATENT LAW REFORMS.

THE policy of the Patent Law has been very well described as a reward to those who devote themselves to the improvement and advancement of the manufacturing arts, granted in the form of an exclusive privilege of limited duration in return for the benefit conferred upon the community by the disclosure of some new and useful invention, which, on the expiration of the term of exclusive privilege, the public at large will be at liberty to freely exercise and enjoy. The principle thus defined is purely arbitrary and artificial; it is a voluntary bargain. The right and property which, according to some persons, a man should have in the creations of his own intellect are not recognised in our patent laws. Such a right is advanced in the law of copyright, and a copyright certificate is a mere matter of form compared with a patent. While occasionally an invention is made which may be said to be creative, by far the greater number are modifications, developments, or improvements on existing objects or processes, and for this reason, if for no other, the protection offered by the State must be of a very different nature from that which is given to works of literature or art. The majority of the agitators for patent reform seem to imagine, however, that every inventor has a property in his idea, and that the patent is a registration accompanied by a tax, and that an inventor owning an idea as he would own a piece of land, registers and pays a tax which gives him a title to his idea, just as might be in the case of land. This mistaken view of the principle of a patent

Hosted by Google

is the only excuse that we can find for the unending proposals for patent reform. On certain of these proposals, Mr. W. Lloyd Wise has contributed some interesting notes to a recent number of the *Chamber of Commerce Journal*. From these notes, which we reprinted in our last issue, we have taken the definition quoted above.

The recent reduction in patent fees may be regarded as a concession to this agitation for reform, and, as Mr. Lloyd Wise observes, it would be well to give the present system a fair trial before going any further. We are inclined, however, to take up a more decided attitude than this, and to deprecate any additional reduction; for if a patent is not worth £5 a year to the owner at the end of four years, and £6 at the end of five years, and so on, it must either be that the invention in its present form is not marketable, or that the inventor or owner of the patent is not making proper use of his privileges, and it would be better that the idea should be thrown open to the public who may, perhaps, be able to make more use of it than its author can or cares to do. There, is perhaps, some justice in the complaint that patent fees are treated as a source of revenue, but this is silenced, at all events for the present, by the construction of the new buildings and library; the formation of provincial libraries, the reconstruction of the index on a uniform plan, and the bringing up and keeping up the abstracts to within six months of date would be excellent objects to apply the surplus to in future.

Already we have rather too many patents, and the protection which was intended to relieve the inventor of competition is used too often for very different purposes. We suffer in this country from patentees who sow the seed, and stand by while others not only begin to till but to reap, and who then come forward to claim the fruits as theirs. In America the monopoly-mongers use patents as powerful weapons, and to increase the number of petty patents would lead to frivolous restrictions and vexatious black-mail.

A patent is meant to be worked, and not to be kept until it can be used for extracting royalties or, perhaps, damages from others who have been actively engaged on the same lines. In most countries, a patent must be worked or the patent lapses. This is an excellent idea but very difficult to apply. An assistant of doubtful competence may be sent abroad, with instructions to "work the invention" in his bedroom at an hotel. We know of one, competent, indeed, to make glow-lamps in a laboratory or lamp-factory, but who "worked the invention" under great difficulties abroad, carbonising filaments in his bed-room stove. It is a pity that patents should lend themselves to such tricks, when copyrights are comparatively free from them. The plagiarist is a clumsy thief compared with the adroit ingenuity and subtle craft of the infringer of patents; but the difference cannot be explained by any theory of proprietorship. There is a sweet simplicity about copyright. What would be the analogue of a mechanical equivalent; would anything of the nature of a "fishing" or of an "omnibus" patent be possible in literature or art? An author need not, at all events, trouble himself about conformity between "provisional" and "complete," or trouble himself about "claims." A patent being a bargain, it is not necessary to inquire into the real reason for any special terms, as distinguished from the formal or perfunctory reasons. The decision that a United States patent, applied for after similar application in foreign countries, lapses on account of the lapse of foreign patents whether by invalidation, expiry of term, or non-payment of renewal fees, may or may not be good American law; but there is no fairness or unfairness about it, unless, indeed, the patentees, buyers, sellers, licencees, infringers, and the general public have a right to know how long a patent has to run. An owner of an English patent need only be careful to pay his fees, and he may be sure that his patent will stand, for whatever it may be worth, for the whole period of fourteen years. The limitation of American and certain other patents to the term of foreign patents is arbitrary, and is said to defy justification or excuse. The same limitation existed in our own patent law prior to 1883, whence it was copied into foreign systems. The result of this simultaneous happy despatch of American and foreign patents, as affecting the American telephone patents, is referred to by our New York correspondent in another column.

OBITUARY.

CHARLES VICTOR DE SAUTY.

We regret to have to record the death, at the age of 63, of Mr. Charles Victor de Sauty, which took place from paralysis on the 11th inst. at Gibraltar, where he was Superintendent of the Eastern Telegraph Company.

The deceased was born in 1830, and after some time spent in a solicitor's office, entered the Submarine Telegraph Company's service. In 1856 he joined the original Atlantic Telegraph Company, and was Superintendent of the Newfoundland Station during the short period the cable worked in 1858, and in the laying of which cable he took part as electrician. In 1859 he joined the firm of Glass, Elliot and Co., afterwards the Telegraph Construction and Maintenance Company, as their chief electrician, and was engaged upon all the expeditions for the laying of that firm's cables up to 1865, including the Atlantic cable of that year. He then went to New Zealand, and was in charge of the Government Telegraphs there until 1870, when he entered the service of the Falmouth-Gibraltar and Malta Telegraph Company, which was afterwards amalgamated, with three other cable companies, into the Eastern Telegraph Company. Although Mr. De Sauty had no regular training in that direction, he was a most ingenious mechanician and kept well in the van of all the early developments of electrical science and submarine telegraphy, in proof of which may be cited his method for the comparison of electrostatic capacity, which was the earliest differential method used for that purpose and contained within it the elements of the duplex. Mr. De Sauty was largely concerned in the practical development of the duplexing of cables which was finally perfected by the introduction of Dr. Alexander Muirhead's condensers. His name was better known on the American side, in connection with the laying of the first Atlantic cables, than that of any other member of the scientific staff, as is evidenced by the quaint verses of Dr. Oliver Wendell Holmes which we have reproduced below. Mr. De Sauty was a man of strong personal character, expressing his opinions very plainly, and one of the staunchest friends it was possible to have. His loss will be regretted by a wide circle of acquaintances.

DE SAUTY.

AN ELECTRO-CHEMICAL ECLOGUE.

Professor. *Blue-Nose.*

PROFESSOR.

Tell me, O Provincial! speak, Ceruleo-Nasal!
Lives there one De Sauty extant now among you,
Whispering Boanerges, son of silent thunder,
Holding talk with nations?

Is there a De Sauty ambulant on Tellus,
Bifid-cleft like mortals, dormient in nightcap,
Having sight, smell, hearing, food-receiving feature,
Three times daily patent?

Breathes there such a being, O Ceruleo-Nasal?
Or is he a *mythus*,—ancient word for "humbug,"—
Such as Livy told about the wolf that wet-nursed
Romulus and Remus?

Was he born of woman, this alleged De Sauty?
Or a living product of galvanic action,
Like the *acarus* bred in Crosse's flint-solution?
Speak, thou Cyano-Rhinal!

Hosted by Google

BLUE NOSE.

Many things thou askest, jackknife-bearing stranger,
Much-conjecturing mortal, pork-and-treacle-waster !
Pretermit thy whittling, wheel thine ear-flap toward me,
Thou shalt hear them answered.

When the charge galvanic tingled through the cable,
At the polar focus of the wire electric
Suddenly appeared a white-faced man among us :
Called himself "DE SAUTY."

As the small opossum held in pouch maternal
Grasps the nutrient organ whence the term *mammalia*,
So the unknown stranger held the wire electric,
Sucking in the current.

When the current strengthened, bloomed the pale-faced stranger,—
Took no drink nor victual, yet grew fat and rosy,—
And from time to time, in sharp articulation,
Said, "*All right !* DE SAUTY."

From the lonely station passed the utterance, spreading
Through the pines and hemlocks to the groves of steeples,
Till the land was filled with loud reverberations
Of "*All right !* DE SAUTY."

When the current slackened, drooped the mystic stranger,—
Faded, faded, faded, as the stream grew weaker,—
Wasted to a shadow, with a hartshorn odour
Of disintegration.

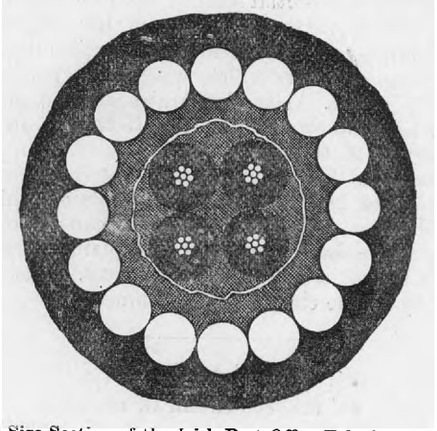
Drops of deliquescence glistened on his forehead,
Whitened round his feet the dust of efflorescence,
Till one Monday morning, when the flow suspended,
There was no De Sauty.

Nothing but a cloud of elements organic,
C. O. H. N. Ferrum, Chlor. Flu. Sil. Potassa,
Calc. Sod. Phosph. Mag. Sulphur. Mang. (?) Alumin. (?) Cuprum (?)
Such as man is made of.

Born of stream galvanic, with it he had perished !
There is no De Sauty now there is no current !
Give us a new cable, then again we'll hear him
Cry, "*All right* ! DE SAUTY."

THE IRISH TELEPHONE CABLE.

On the 4th inst. Her Majesty's Post Office telegraph ship "Monarch" successfully laid a new cable, containing four conductors of special size, designed for telephonic use between Great Britain and Ireland. The cable was laid between Port Kail on the Scotch Coast and Donaghadee on the Irish coast. The engineering staff of the Post Office has been busily engaged during the last eight months in erecting the land wires, and the cable connections having been completed on Thursday last



Full Size Section of the Irish Post-Office Telephone Cable.

week, the wires were tested by Mr. J. C. Lamb and Mr. W. H. Preece. Conversation was carried on with perfect ease and freedom between Belfast and Glasgow. Amongst the first to speak between Glasgow and Belfast were: Lord Kelvin, Sir John Purvis, the Lord Provost of Glasgow, and Sir Daniel Dixon, Lord Mayor of Belfast, all of whom expressed their gratification with the great success of the new communication.

To ensure that the go and return land wires shall preserve the same mean distance from disturbing causes, they are made to exchange their positions, as in the case of the London-Dover section of the London-Paris line, by revolving round each other like the strands of a rope over the whole distance, about seven complete twists being made in every mile. The cable wires are twisted in a similar manner. At present only the Belfast-Glasgow circuit is completed, but a second pair of wires is erected as far as Stranraer on the way to Manchester, Liverpool, Leeds, and eventually London; whilst a pair is also just being commenced to Dublin, and will ultimately be extended to Cork. The Belfast-Glasgow line will be opened very shortly to the public. The charge for a conversation of three minutes will be 5s. The tariff for the London-Paris line is, it will be remembered, 8s. for a similar period.

The Belfast-Glasgow line is 150 miles long, and the cable 23½ nautical miles. The London-Paris line is 303 miles long, and its cable 21 nautical miles. Both cables are made to practically the same specification. The conductors are of 160lb. copper, and the dielectric 300lb. gutta percha; the electrical resistance at 75°F. is 7½ ohms, and the electrostatic capacity ·3 micofarad per nautical mile of 2,029 yards. Both cables have been made by Messrs. Siemens Bros. and Co. There is one point alone in which they differ. Surrounding the core of the Irish cable there is, as will be seen by our illustration, a sheathing of brass tape, intended to protect the conductors from the ravages of the teredo. This has not been considered necessary in cables laid heretofore in British waters, but the teredo has now made its appearance here and must be guarded against.

NOTES ON THE INFLUENCE OF ELECTRICITY IN TANNING OPERATIONS.*

BY CONRAD K. FALKENSTEIN.

It has been known for the last thirty years that the application of of an electric current to hides in process of tanning exerts a beneficial effect, increasing the rapidity with which the gelatinous material of the pelt combines with the tannin in the liquors to form leather. Before going further, it may be well to briefly sketch out what occurs when hides are tanned. Ox hide consists roughly of three layers, as follows:—(*a.*) The *epidermis*, consisting of an outer layer which is constantly being shed, and an inner layer, from which the material of the outer layer is supplied. (*b.*) The *pars papillaris*, of close fibre, in and below which are situated the hair sheaths, fat and sweat glands, and the muscles which erect the hair; the upper coat of this layer forms the "grain" of leather. (*c.*) The *pars retcularis* or corium, a network of fibres, which forms the greater part of the section; this is densest near the layer (*b*), the bundles of fibre becoming more open towards the flesh side. When the hide is taken off the animal the exterior of this layer is covered with flesh, fat and tissue.

The first thing to be done is to wash the hide free from all blood, salt, &c., or, if sun-dried or cured, to thoroughly wash and soften it (this is sometimes assisted by mechanical means); when clean and soft it is treated with solutions of lime of gradually increasing strength, which have the effect of swelling up the hide and splitting up or commencing to dissolve the fibres. This action takes place most vigorously at the two surfaces; on the grain side it dissolves away the outer cells or epidermis, and the hair *papilla* or knob of corium, which holds and supplies nourishment to the hair, thus allowing it to be easily scraped off by the blunt unhairing knife; on the flesh side it plumps up the *pars reticularis*, causing it to be easily distinguished (by its firmness) by the flesher from the loose membrane and fatty matter which is to be removed. When the hair and flesh are removed, the hides are washed and worked over on the grain side with a stone or blunt knife to force out the lime solution and the remains of hair, epidermis, &c., which are left in the hair cavities after unhairing; after another washing, the hides are ready for tanning.

Now the hide material or gelatine to be tanned consists of bundles of fibre, each bundle being made up of a refractory base surrounded by gelatinous, tannable fibres, the axes of which lie generally at right angles to the surfaces of the hide. After liming, the fibres are in a swelled condition, both acids and alkalis (with exceptions) having this property of distending the hide and causing it to absorb water. The action of the tannic acid is to displace the water, and, while converting the gelatinous fibres into leather, to maintain the plumpness by an acid reaction after the lime has been neutralised. Other methods are employed for unhairing on the Continent and elsewhere, such as sweating or partial putrefaction, use of sodium sulphide, &c., in which this plumpness has to be produced by the use of sulphuric, acetic, or other acids, or by liquors which contain acetic, lactic acids, &c., through natural fermentation.

* Paper read before the Institution of Electrical Engineers, March 23rd.

Hosted by Google

The hides are then treated with solutions of tannic acid of gradually-increasing strength, until they show a uniform brown colour in a freshly cut section (lighter or darker according to the tanning materials employed), and have the necessary firmness and weight. Care must be taken as to the rate at which the tannic acid solution is increased in strength, for if, after the tannage is fairly commenced and the lime neutralised, the hides be not fed with stronger and stronger liquors, they lose their firmness and are said to "go back," after which a species of putrefaction is set up in the interior untanned portion of the hide which causes adjacent bundles of fibre to unite, thus destroying the open fibrous structure of the hide, and practically stopping diffusion; this result may also be produced by using too strong liquors at first, which bind up the pores and prevent liquor from reaching to the interior.

For dressing leather somewhat different methods are followed, but the same precautions must be taken in working the liquors as just described.

The above is the process to be gone through, the functions of the electric current being:—(1.) To increase the rate at which liquor diffuses itself through the hide by endosmose effects. (2.) To increase the chemical activity of the reaction by molecular vibration.

Many methods of applying the current have been proposed, some depending upon the action of the gases evolved at the electrodes, and others upon the endosmose and molecular effects of the current on the hides and liquor. M. Gaulard patented a process in 1883, making use of the first method, the hides being suspended in a pit, from the perforated false bottom of which is sent, first, a stream of hydrogen from the kathode; after eight days the current is reversed, and the hides subjected to the action of a stream of oxygen until they are tanned. The other method, which has been employed by Gaulard, Landin and Abom, De Meritens, and others, is to use a pit with electrodes on opposite sides, and pass the current through the liquor and suspended hides at right angles to their surfaces. When the hides are struck through, they are transferred to the layer pits where they are put in alternate layers with ground bark, &c., liquor being run in either before or afterwards. The current is now applied by electrodes placed one underneath and one on top of the pile, the positive pole generally at the bottom. This laying away is repeated until the hides are tanned. By thus applying electricity to the ordinary methods of the tannery, the time necessary for tanning heavy sole leather may be reduced from 120 to 45 days, as proved by the practice of Messrs. Landin and Abom in Sweden, and De Meritens at St. Petersburg. Messrs. Landin and Abom use alternating currents. If now the electrical action be assisted by suitable mechanical agitation of the liquor and movement of the hides, so as to mix the liquor which has passed through the hide with that remaining in the vat, we shall obviously have an increase in the rate at which the tannage proceeds.

Several processes have been devised to combine the effects of the electric current and motion, amongst which may be mentioned those of Messrs Worms and Balé, L. Groth, and others. Mr. Groth employs a vat, in the centre of which is a rotating or reciprocating (according to the shape of the vat) frame, on which are suspended the hides or skins to be tanned, an electric current being passed from one side of the pit to the other, through the liquor and hides. This process reduces the time necessary to tan a hide to about 28 days.

Messrs. Worms and Balé's system combines the application of an electric current with the use of a rotating drum; the drum is about 11ft. in diameter and provided with internally-projecting pegs; in operation it is nearly half filled with liquor, and the hides being put in (one by one), the drum is closed and rotated; while in motion an electric current is applied by electrodes, so disposed as to fill the liquor with, and hence subject the hides to, a uniform field of endosmotic force. When the drum is in motion, the hides, floating in the body of the liquor, are turned over and the liquor mixed, the bottom layers being continually brought to the top by the skin friction. Under these conditions, running continuously, hides may be tanned in about 100 hours. It will be seen that the rotating drum contains four variable factors:—(1) The strength and disposition of the electric current; (2) The speed of rotation; (3) The proportional amount of liquor in the drum; (4) The length and number of the projecting pegs, thus giving the system considerable flexibility of treatment. It has now been worked on a commercial scale for some years by the British Tanning Company (Limited) in London, by MM. Brion et Dupré, in Paris, and also in America.

Considering the purely electrical and chemical effects on the hides and liquor, the final result established by the experiments of Messrs. Rideal and Trotter, Prof. Müntz, of Paris, Dr. Foelsing, Dr. Zerener, and others is that raw hide is capable of combining with its equivalent weight of tannic acid in from 4 per cent. to 38 per cent. (according to the process employed) of the time taken when electricity and apparatus, or electricity alone is not applied.

Below I give particulars of some experiments which I have made, bearing on the action of the electric current. Let us first consider what happens when a current is passed through a carefully filtered solution of tannic acid, made from an oakwood extract, using platinum electrodes. The cell employed was divided into three by two porous clay diaphragms, each compartment being of equal capacity, 200 c.c., and containing 150 c.c. In the first compartment was placed the anode, and in the third the kathode, the intermediate one completing the circuit. A current of 0·0024 ampere was applied at a potential difference of 7 volts. On completing the circuit the following actions took place: at the anode bubbles appeared and collected round the wire as a straw-coloured froth; at the kathode there was considerably more evolution of gas, and the froth produced was darker in colour and showed streaks of dark red colouration radiating from the wire. After passing the current for 90 hours it was stopped, and the electrodes and liquor examined. The anode had a small quantity of soft, brown precipitate on its surface ($\frac{3}{8}$in. × $\frac{3}{8}$in.) which was easily soluble in warm distilled water, and was absorbed by hide powder; the kathode was covered closely with a hard, dark-brown coat of precipitate to the depth of from one sixty-fourth inch to one thirty-second inch at the edges. This precipitate is insoluble in hot distilled water, but is immediately dissolved on addition of a very small quantity of H_2SO_4, forming a clear tan-coloured solution which is bleached on treatment with hide powder, thus proving the precipitate to be a dark, tanning, colouring matter. On examining the liquid in the three compartments, No. 1, containing the anode, was as clear as at the commencement of the experiment, so was No. 2, both having a slight coat of tannin anhydride on the bottom; No. 3, containing the kathode, was somewhat turbid with dark-brown particles which were soluble in hot distilled water and absorbed by hide power. At the end of the experiment it was found that in the compartments 1 and 2 the level of the liquid had fallen and in 3 it had risen.

The above gives a general view of the action which I have amplified as follows:—I. To compare the endosmose effects in solutions of tannic acid, at varying potential differences, at varying strengths of tannic acid, and with diaphragms of different materials. II. To compare the precipitation of anhydride, &c., in solutions of tannic acid, when a current of electricity is passed through them, and when allowed to remain during the same time and under the same conditions but without passing a current. III. To examine the amount of tannin in the liquor before and after passing an electric current.

I.—*Endosmose.*

Cells were made consisting of two ebonite boxes (each having one side cut away) fastened together with a plate of porous clay or leather between them, thus forming two compartments, joined through a porous diaphragm, each having a capacity of 200 c.c. In experimenting, 100 c.c. of the liquor to be examined was placed in each compartment and the current applied from accumulators, &c., through platinum electrodes, and the variation of level with time noted; the top and bottom surfaces of the cells were made parallel and carefully levelled during experiments. Between each set of readings the clay diaphragm was cleaned and allowed to soak in water, so that the mechanical resistance to flow of liquor might remain as nearly constant as possible.

This method was adopted as the apparatus is simple, and if differences of level between the two sides of the diaphragm be considered, evaporation errors are eliminated, as the surfaces exposed to the air are equal in both compartments.

The first experiments undertaken were to see in what way the rate of flow varied with the difference of potentials applied, the results of which are shown in the following curves:—

Curves and **Table A_1** *and* **A_2**.

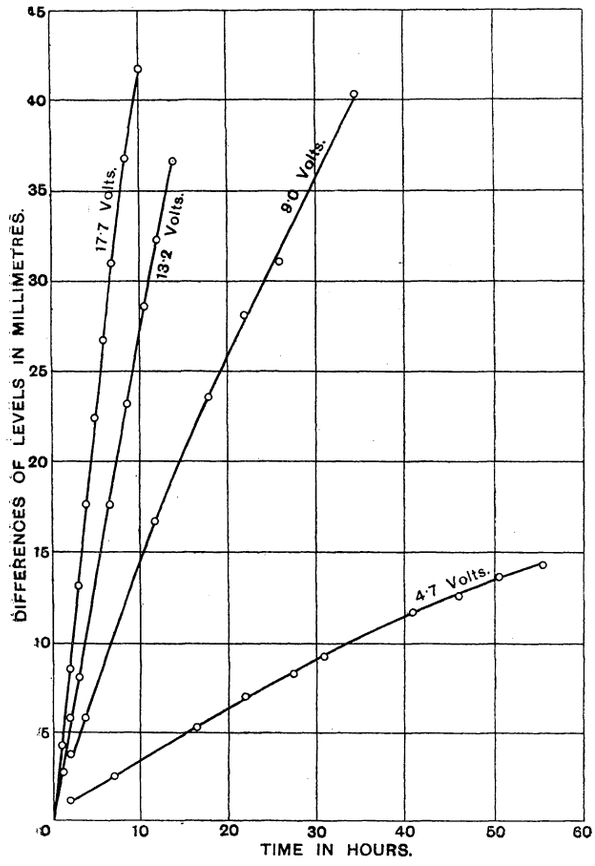
I.	II.	III.	IV.	V.	VI.	VII.
Volts.	(Volts)^2.	Tangent to curve.	Mean current by voltameter.	Proportional rate of flow.	Calculated rate of flow.	Proportional current.
4·7	22·09	0·27	0·00089 A	0·22	0·27	0·13
9·0	81·00	1·22	0·0066 ,,	1·00	1·00	1·00
13·2	174·24	2·71	0·0162 ,,	2·22	2·15	2·45
17·7	313·29	4·42	0·0274 ,,	3·62	3·86	4·15

From A it may be seen that:—(1) with an approximately constant mechanical and electrical (at one voltage) resistance, the rate of flow of the liquor varies at a higher rate than simple proportionality to the voltage between electrodes (*see* columns I. and V.); (2) the current varies at a slightly higher rate than the rate of flow, as measured by tangent to curve (*see* columns V. and VII.: *see also* curve A_2); (3) the rate of flow approximately varies as the square of the voltage (*see* columns V. and VI.).

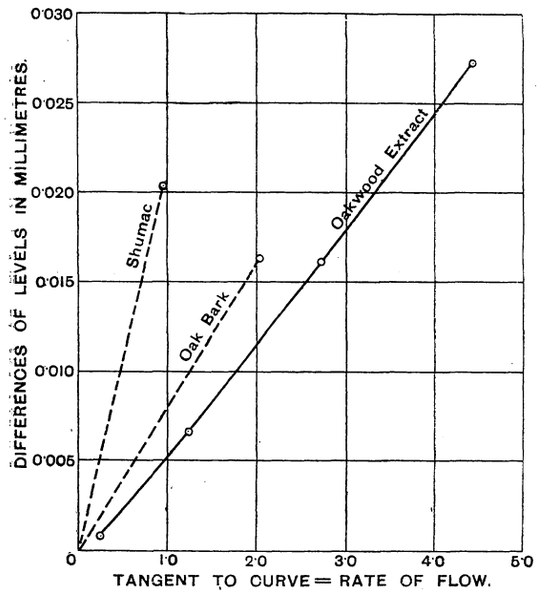
In order that Ohm's law may be satisfied, it follows that the resistance of the tan liquor examined must vary inversely as the potential difference applied. In some experiments I am making on this point, I find that between certain limits of current density

Hosted by Google

the resistance varies inversely as the electromotive force, but after the solution has been subjected to electrolysis for some time at the higher current density it loses its power of offering an increased resistance to a lower potential difference, the resistance remaining fairly constant at the minimum value for all potential differences below the high one which broke it down. This, taken in

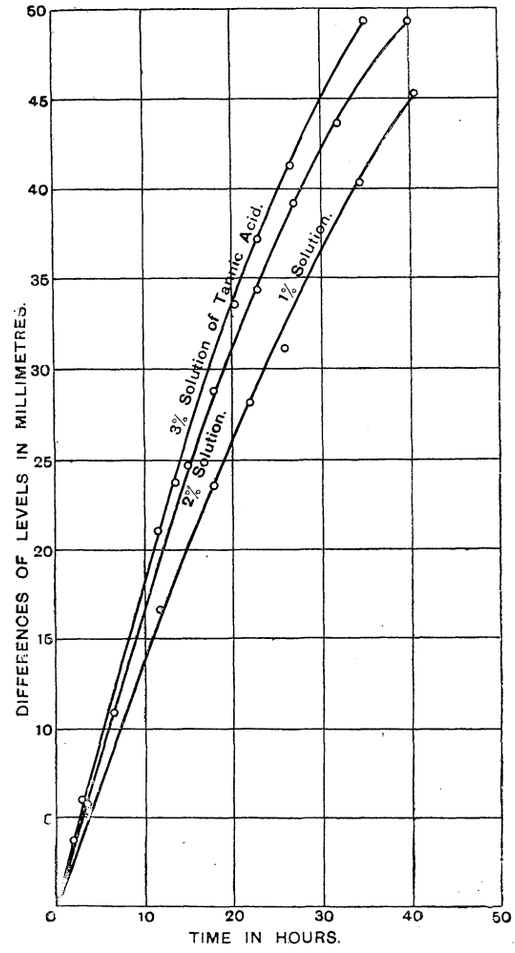


CURVES A.—1 per cent. Solution of Tannin.



CURVES A_2.

conjunction with the results given in Division III., points to an alteration in the structure of the tannin molecule being produced by electrolysis, the resinous dark tanning matter being separated in the form of insoluble precipitate on and about the kathode, the remaining liquor being of higher electrical conductivity and clearer, the amount of available tannin remaining constant although in separate forms. The next experiments were made to find in what way the rate of flow varied with the percentage of tannin in the solution at constant potential difference and using the same porous diaphragm in each case.

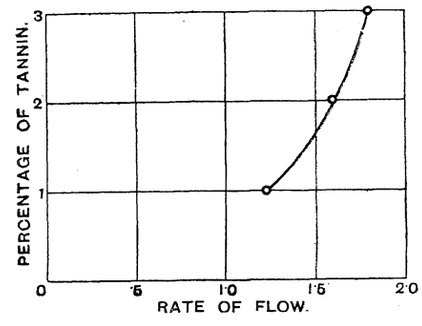


CURVES B.—P.D. = 9·0 volts.

Table B.—*Curves* B_1 *and* B_2.

Percentage of tannin.	Volts.	Mean current.	Rate of flow.	Proportional rate of flow.	Proportional current.
1	9·0	0·0066 amp.	1·22	1·00	1·00
2	9·0	0·0079 ,,	1·60	1·31	1·19
3	9·0	0·0109 ,,	1·80	1·47	1·65

From the above it will be seen that the rate of flow (as measured by tangent to curve) increases with the strength of the liquor. This fact is specially important for the following reason: In ordi-



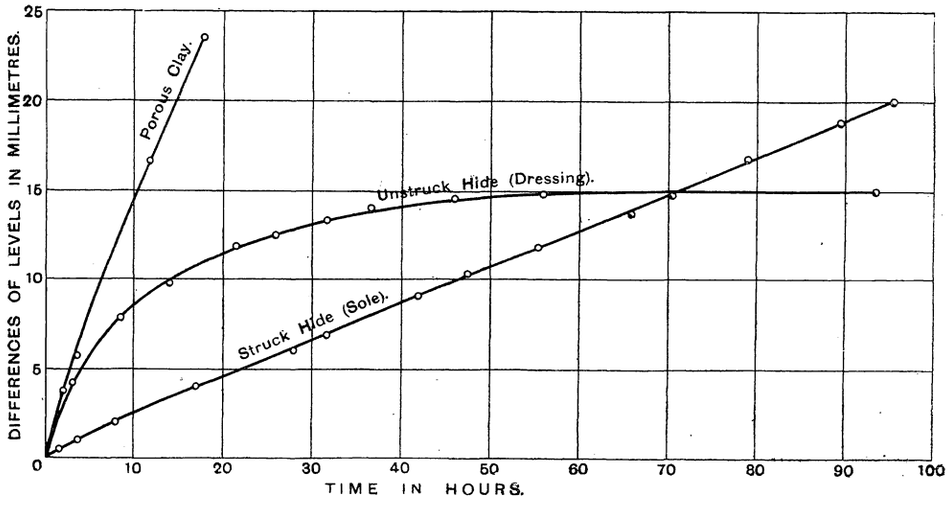
CURVE B_2.

nary tanning operations it is well known that the greater portion of the gelatine is combined in the first month or so of the tannage, the remainder of the time being spent in tanning the middle layers and giving weight, owing to the increased resistance which the outer tanned portions offer to diffusion. Now, for reasons given earlier in the Paper, it is necessary to use liquors of gradually increasing strength as the tannage proceeds, and which, for any given potential difference, give (as shown in curve B_2) an increasing

Hosted by Google

hydrostatic pressure or head tending to force the liquor through the hide; thus there is a kind of self-regulating arrangement, viz. :—as the mechanical resistance of the hide increases, so the endosmotic pressure increases to overcome that resistance.

The next experiments were made using diaphragms of different materials and keeping potential difference and strength of liquor constant, the results being shown below :—



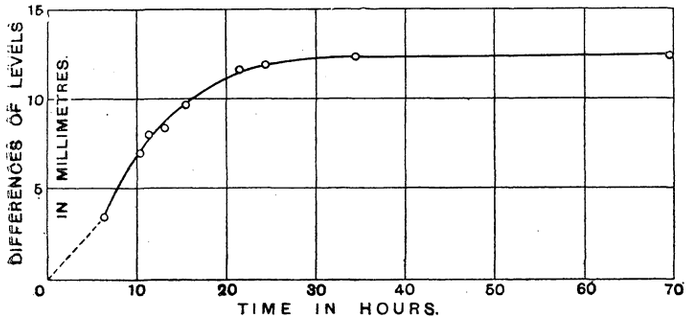
CURVES C.—1 per cent. Solution of Tannic Acid. P.D. = 9·0 volts.

Table C.—*Curves C.*

9 volts. 1 per cent. solution of Oakwood tannin.

Diaphragm.	Mean current.	Rate of flow.	Proportional current.	Proportional flow.
Struck sole	0·0041 *a*	0·20	0·62	0·16
Porous clay	0·0066 „	1·22	1·00	1·00
Dressing hide	0·0106 „	1·58	1·60	1·29

In the above will be noticed the great difference in mechanical resistance to diffusion between leather before and after it has been struck (*i.e.*, smoothed down and worked over with the striking pin) and rolled. The curious bending over of the curve for unstruck hide is due to the influence of the head of liquor and openness of the pores allowing the liquor to run back again, a certain point being reached at which this leakage becomes equal to the flow and the difference of levels remains constant. This effect is also shown in Curve D with tap water and a porous clay diaphragm.



CURVE D.—Porous Clay Diaphragm. Tap Water. P.D. = 7·2 volts.

Curve D.

The next experiments were made, using liquors prepared from different tanning materials, and keeping the potential difference constant and using the same porous clay diaphragm, the results being shown below :—

Table E.—*Curves E.*

9 volts. 1 per cent. solutions.

Liquor.	Mean current.	Rate of flow.	Proportional current.	Proportional flow.
Distilled water	0·00078	0·095	0·12	0·077
Shumac	0·0204	0·97	3·09	0·79
Oakwood extract.....	0·0066	1·22	1·00	1·00
Oak bark	0·0164	2·02	2·48	1·65

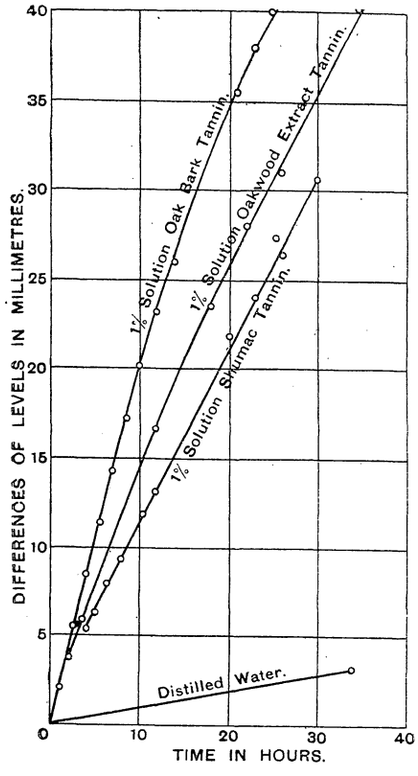
In the above curves 10 mm. difference of levels corresponds to 11·36 c c. passing through the diaphragm, the levels in both compartments being the same on starting experiment.

II. and III.—*Chemical Action.*

II. To compare the precipitation of anhydride, &c., in solutions of tannic acid when a current is passed through them, and when allowed to remain during the same time and under the same conditions but without passing a current.

III. To determine the amount of tannin in the liquor before and after passing an electric current.

In carrying out the above, two beakers were taken in each of which 150c.c. of tan liquor (containing 5 per cent. oakwood tannin) was placed. Through the liquor in one beaker a current of 0·0086



CURVES E.

ampere (measured by voltameter) was passed for 96½ hours, and the other was allowed to stand open by its side, being thus under exactly the same conditions, excepting that it had no electricity passed through it.

Hosted by Google

In the analyses below :—
33·4 c.c. of permanganate = 10 c.c. n/10 crystallized oxalic acid.
17·6 ,, ,, = 20 c.c. indigo carmine.

No.	Description of liquor.	10 c.c. infusion.	10 c.c., after hide powder.	C.c of non-tannin.	Tannin %.	Non-tan' in %.
I.	Liquor before experiment	32·75	19·5	1·9	5·007	0·69
		32·70	19·4	1·8		
II.	After exposure, without passing electric current.	32·50	19·55	1·95	4·88	0·72
		32·45	19·50	1·9		
III.	No. II., filtered	32·15	19·45	1·85	4·79	0·69
		32·15	19·45	1·85		
IV.	After passage of electric current and exposure ...	32·5	19·0	1·4	5·073	0·54
		32·5	19·1	1·5		
V.	No. IV., filtered	31·0	18·9	1·3	4·57	0·48
		31·0	18·85	1·25		

The same solutions were used throughout the above experiments ; 10 c.c. of a diluted solution (1-20th) were titrated with permanganate in presence of indigo carmine before and after treatment with hide powder. On examining the above results we may notice :—(i.) The action of the electric current on bodies which are absorbable by hide powder. (ii.) The action of the electric current on bodies which are not absorbable by hide powder.

(i.) On comparing Nos. I. and IV. it will be seen that the total amount of tannin remains unaltered, or, if anything, slightly increases after the passage of the current. On filtering IV. and again analysing, it will be seen that some of the tannin has been precipitated (*see* V.), probably as anhydride or phlobaphene. This precipitate, as seen from the experiment with the three-compartment cell, is produced at the kathode by the action of the hydrogen evolved there ; this tannin is proved by column IV. to be still available for tanning purposes (after heating).

(ii.) This action is very marked, as will be seen from examination of columns 5 and 7 in table above, the number of c.c. of permanganate consumed by these non-tannin bodies goes down from 3·7 in the original liquor to 2·9 in the unfiltered electrolysed solution, and to 2·55 in the filtered ; this reduction is really greater than is apparent here, because the electrolysed solution was exposed to the air for exactly the same time as the other, and therefore the increase of 0·15 c.c. produced by exposure in the non-electrolysed should be added. This leads one to think that there may be a kind of restoration of the liquor, the tannin which has been decomposed by exposure to the air being reduced, possibly by the nascent hydrogen at the kathode; this would account for the reduction in the quantity of non-tannin matters, although, if these were more easily oxidisable than the tannin, the oxygen evolved at the anode might influence this result.

Summary.—The principal chemical actions of the current on tan liquor, using platinum electrodes at a current density of 1·6 ampere per square foot, are :—1. Precipitation of anhydride of tannin ; this precipitate is more copious with a tannin capable of yielding "bloom," as shumac, in which case the electrical conductivity is higher (*see* Table E). 2. Reduction of the amount of non-tannin matters in the solution. The above shows that, at all events below current densities of 1·6 ampere per square foot, a limit which is never exceeded or reached in practice, there is no loss of tannin due to the action of the electric current as the ratio $\left(\frac{\text{number of ampere-hours}}{\text{number of c.c. of liquor}}\right)$ in this experiment is considerably greater than that employed in practice—say 366 : 1. I have found that the solubility of the precipitate decreases as the current density increases. There is an effect (referred to earlier in the Paper) which doubless influences the rapidity at which the gelatine and tannin combine—viz., the molecular vibration of the liquid and hides, due to the phenomenon of electricity being a vibration of the ether, agitating the particles and making them combine with their affinities sooner than they would do if left to themselves. In support of this, the fact of tanning operations being accelerated by rise of temperature may be brought forward, heat being a similar vibration of the ether, differing only in period from the electrical vibration.

In endosmose, however, we have a perfectly tangible, measurable effect, propelling the liquor in the direction of the lines of current flow, tan liquor also being a particularly favourable medium for his purpose for the following reasons :—1. The force increases with the percentage of tannic acid in the solution, thus falling in with the practical methods of tanning—*i.e*, increasing as the permeability decreases. 2. The electrical resistance of tan liquor being high, the necessary difference of potentials (to the square of which the endosmotic flow is proportional) can be obtained between adjacent portions of the liquid without an undue expenditure of current, and, therefore, of energy.

We might approximately calculate how much tannin would be likely to pass through a 20lb butt (tanned and dry wt.) in an hour, using, say, a 12-ampere current at 9 volts, with proportionally larger electrodes, but keeping the distance between electrodes and hide the same, as in Experiment C with unstruck hide (it must be remembered that the leather in question was fully tanned, and therefore its permeability was at its minimum value).

Area of butt = 54″ × 66″ = 3,564 square inches.

Working area of diaphragm = $2\frac{5}{8}$ square inches.

Tangent to curve near origin = $\frac{10\text{mm.}}{6{\cdot}3\text{ hours}} = \frac{11{\cdot}36}{6{\cdot}3}$ c.c. per hour.

Current in experiment = 0·0106 ampere.

One gallon = 4,536 c.c.

Increasing the current to 12 amperes, and assuming (from Table A and curve A_2) that the flow is proportional to the current, we have $\frac{11{\cdot}36 \times 12}{6{\cdot}3 \times 0{\cdot}0106 \times 4{,}536} = 0{\cdot}45$ gallon of liquor passing through the butt per hour ; this, supposing the liquor to contain 4 per cent. of tannin and to have a specific gravity of 1·02, would be equivalent to $\frac{0{\cdot}45 \times 10 \times 1{\cdot}02 \times 4}{100} = 0{\cdot}1836$lb. of tannin. If the butt require $20 \times 0{\cdot}45 = 9$lb. tannin to tan it, then this amount would pass through in 49 hours. From the above it will be seen that, having a means of bringing the liquor into intimate contact with the fibres of the hide and also of assisting it to combine whilst passing through, we are in a much more favourable position than when working with only diffusion and capillary attraction to bring the liquor to the interior and replenish it when exhausted, especially as the tannage proceeds and the hide becomes less and less permeable.

In conclusion, I must express my thanks to the British Tanning Company (Limited) for facilities granted in carrying out experiments and permission to publish results.

On sheet A_2 is shown the variation of rate of flow, with current, for three different tanning materials, the curves for oak bark and shumac being taken from the results given in Table E, from which it will be seen that the relative velocities imparted by the current to 1 per cent. infusions of oakwood extract, oak bark and shumac, are approximately as $3\frac{1}{4}$, $2\frac{1}{2}$ and 1, the endosmose effect being smallest on the shumac infusion, which is, however, one of the most rapid tanning materials, and therefore needs the least extraneous assistance. We have thus, to some extent, a means for separating tannins from a mixture of various different tannins, since, with the same current, different tannins move at different velocities in the same electrolyte ; the application of electric endosmose to similar problems was, however, suggested by Dr. Silvanus Thompson in his contribution to the Discussion on Mr. Swinburne's Paper on "Problems of Commercial Electrolysis," last November.

DISCUSSION.

*Mr. SWINBURNE cordially congratulated Mr. Falkenstein on the Paper, which seemed to be full of most important information. It was a very important Paper ; but it was one that he could hardly discuss without having seen it before.

*The PRESIDENT, in proposing the usual vote of thanks to the author, said that it was a great advantage to the Society that they had from time to time brought before them new and fresh subjects. Many of the members of the Institution seemed to labour under the impression that the whole of the electric world was contained in the magnetic field of a dynamo, and it was just as well that sometimes they should find that there were other people in this world who were studying other forms of electrical agency and electrical action, and that in no respect did the application of electricity to such a process as tanning detract from the extreme interest which the members of the Institution should feel in every practical application of electricity.

LEGAL INTELLIGENCE.

Woodhouse and Rawson United (Limited).

Mr. Justice Vaugham Williams on Wednesday had before him three petitions for the compulsory winding up of this Company.

After a lengthy discussion, the petitioners abandoned the applications for a compulsory order in favour of a supervision order, whereupon Mr. UPJOHN, on behalf of a holder of ordinary and preference shares, said his client wished to have an opportunity of presenting a petition.

His LORDSHIP said on the 29th inst. a new rule came into force which would enable him on the hearing of any petition, if those who presented it abandoned the petition, to substitute another petitioner. He would, therefore, adjourn these petitions until the new rule was in operation.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March* 31, 1893.

The Telephone Patents.—The past week has been signalised by two decisions in the Courts which are likely to have a most important bearing upon the various electrical industries. The first of these was rendered on March 27th in the case of Henry Huber and others *v rsus* the Nelson Manufacturing Company. The question at issue was:—What is the life of a United States patent applied for *after* the same has been applied for in foreign countries, and also after the foreign patent has expired by reason of non-payment of taxes or failure to work? Justice Blatchford, of the United States Supreme Court decided that under those circumstances the United States patent was void. The electrical interest of this decision is connected with the telephone situation, since by this decision the three patents of Edison which broadly cover the use of carbon in telephone transmitters become void. This simplifies the telephone situation, owing to the fact that the only "basic" telephone patent having any length of time to run is the Berliner microphone patent, the validity of which is itself in question before the Courts. Great interest was manifested recently in telephone matters by reason of the expiration of the Blake transmitter patent and the Bell parchment diaphragm telephone patent, and the expiration in January next of the Bell iron diaphragm patent. The Edison patents, however, and the Berliner patent so fully covered the ground of transmitters of the variable contact type that it was a question whether with the lapse of the patents referred to, the telephone business would in fact be open to the public. This led to a close study of the history of telephone development, and this disclosed the fact, long since forgotten by most people, that as early as 1883 telephonic communication was carried on experimentally on grounded circuits between New York and Chicago, and between New York and Cleveland, so that long-distance work, which was thought to be new, is now ten years' old. In these long-distance experiments, which were conducted over a No. 4 compound wire (composed of copper and steel), a large number of transmitters were tried. It is not quite clear that the Bell magneto instrument was actually used as a transmitter between New York and Chicago, though there are some who claim that it was. The Bell instrument was undoubtedly used, however, as a trasmitter over the line from New York to Cleveland, and over many other lines of lesser length, thus showing that it is capable of giving fair transmissions over almost any distances reached at the present day. These lines were said to have been noisy, but this was, of course, no fault of the transmitter, but was probably due entirely to the fact that a grounded circuit was used.

The Edison Feeder Patent.—The second decision relates to what is known as the Edison Feeder Patent. In this patent, which was issued September 19, 1882, Edison claims the use of feeding conductors connecting the consumption circuit with the source of electrical energy, and having no translating devices connected therewith, and extending from a source of electrical energy to the centre of the consumption circuit. As the employment of feeders is almost universal in the distribution of energy over large areas, it will be seen that this patent is very broad. The suit was between the Edison Electric Light Company and Westinghouse, Church, Kerr, and Co., and it was decided by Judge Green, of the United States Circuit Court for the District of New Jersey, in favour of the Edison Company. The Judge, in announcing his decison, merely stated that he had found for the Edison Electric Light Company, and that his decision in full would be published in a few days. Since this judgment has not as yet come to hand, it is not known how broadly the judge construed the patent, and the scope of his decision has given rise to much speculation. The General Electric Company, the present owners of the Edison patent, claim that it covers the use of feeders, not only in the distribution of current for electric light, but also that it covers the use of feeders in the operation of electric railroads and all other applications where the drop of potential is avoided by the use of feeding circuits. The Westinghouse people, however, affect to believe that the decision will have very little importance, that it does not apply to electric railroad feeders, nor to the methods usually in vogue in this country for distributing alternating currents. They claim also that this patent will expire in September of next year by reason of a similar patent which was issued in England in September, 1880. The General Electric Company, however, deny this. Referring to the Edison patent we find that the specification refers more specifically to the use of feeders for incandescent lamp circuits, and the Westinghouse people are inclined to interpret it as being thus limited. However, Mr. Edison in describing his patent uses these words: "This invention relates to a method of equalising the tension or pressure of the current through an entire system of electric lighting, or *other translation* of electric force, preventing what is ordinarily known as 'drop' in those portions of the system the more remote from the central station." It would scarcely seem that without a disclaimer Edison's patent could be limited to electric light distribution, but that it must apply equally to the distribution in a similar manner of current for other purposes. If this broader view is taken by the Court, it not only gives the General Electric Company a more perfect monoply of the lighting business, but will also place within its control all of the method now employed of operating electrical railways except two; these exceptions are the storage battery and the series method of electrical propulsion. The storage battery has been experimented with a good deal in this country for street-car propulsion, but in no case has it met with much success. The series system of propulsion is best known through Prof. Sidney Howe Short's attempts to render it practicable, which, however, were finally abandoned. Prof. Short got just about as far with his series system as Mr. Charles F. Brush did with his arc lighting system up to the time of his discovery of the automatic cut-out, which was the key to success. Prof. Short met with the same difficulties that Mr. Brush did up to that time, and found that while he could operate two or three cars quite economically and successfully, when the number was increased beyond this the difficulties multiplied rapidly. Another inventor taking the subject up at this point and having experience of the Short system has introduced the missing link, namely, the automatic cut-out, and although his plans have never been put into operation, there seem to be no theoretical objections to them, and they certainly possess some valuable features. It seems not unlikely that if the Court takes the broad view of the Edison claims the result will be the development of the series method of distribution for movable translating devices.

CORRESPONDENCE.

HIGH VACUUM TUBES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With regard to Mr. Kerdel's letter published in your last issue, I may remark that I have several times tried placing a vacuum tube between two charged plates and suddenly removing it, hoping to obtain a luminous flash, but was always unsuccessful. Apparently the field at the edges fell off too gradually to allow a sufficiently rapid rate of change of induction through the tube when pulled out of the field by the hand. The other day, however, when showing the experiment of the rotating tube and excited ebonite rod to a friend, I found that when the tube was at rest on removing the rod suddenly there was a distinct flash in the tube. The same happened when the rod was suddenly approached or moved past the tube. Another form of this experiment is to take a straight tube (mine was about 5in. long and $\frac{3}{4}$in. in diameter) and rub it on a piece of flannel laid flat on the table, the whole of the tube being on the flannel; nothing much will happen in the way of luminosity so long as the tube is in contact with the flannel, as, of course, the electric induction passes from the outer surface of the glass straight to the flannel, which is practically in contact with it, and

Hosted by Google

does not go through the rarefied gas. On suddenly lifting the tube some of the induction will pass from the charged surface of the glass through the tube, and will cause a fairly brilliant flash in the tube.

Obtaining a luminous glow on rubbing an exhausted tube or bulb with a piece of silk or flannel is a very old electrical experiment, and has, I expect, been put to practical use before now for the purpose of obtaining (so-called) spirit lights by unscrupulous mediums at dark *séances*.—Yours, &c.,

E. C. Rimington.

The Park, Norwood, S.E., April 7, 1893.

CONDENSING FOR ELECTRIC LIGHT STATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Assume that all the engines in a station are of the same size. The smaller the size the smaller will be the steam consumption. Let the year's load curve be covered by these engines, the number of engines running at any time being suitable to the load. The result can be expressed by an annual number of engine-hours (n). The lbs. of steam per hour (p), used non-condensing, that are saved by condensing are constant for all loads on the engine. The total saving of steam is np. The lbs. of steam per hour (P) required to run the engine non-condensing, at full speed, excited are constant for all loads. n P lbs. of steam are required to run the engine excited. Each unit costs a constant additional number of lbs. of steam per hour (π). If the year's units be ν, total steam consumption is $n\,\mathrm{P} + \nu\,\pi$ non-condensing.

The proportion of the saving by condensing to non-condensing consumption is $\frac{np}{n\mathrm{P} + \nu\pi}$ = one-fifth about. The steam used in the engines is produced by five-sixths or six-sevenths of the coal burnt, the remaining one-sixth or one-seventh being utilised in keeping stand-by boilers warm. These two figures correspond to the cases of Kensington and Millbank respectively, from tables given by Mr. Crompton and Prof. Kennedy. The saving of coal can then be tabulated as the percentage of the total amount, used non-condensing, that would be saved by condensing.

Ratio condensing to non-condensing plant.	Percentage of total coal saved.	
	Apportioned to engines.	
	$\frac{5}{6}$	$\frac{6}{7}$
$\frac{1}{5}$	8·88	9·14
$\frac{2}{5}$	12·7	13·
$\frac{3}{5}$	13·9	14·3
1	16·66	17·1

Prof. Kennedy's figures were for the summer, and Mr. Crompton's for the winter, so the results may be averaged. With a condensing plant capable of maintaining a suitable vacuum at full load, 17 per cent. of the total coal consumption is saved, and this applies to carting, shovelling, and removing ashes—17 per cent. of the water is saved.

The rate of saving of steam being 18 per cent. at full load, $\frac{1}{5}$ of the boiler power is saved. This leads to some saving from stand-by losses, and since the rate of saving at no load is as much as 40 per cent., obviously a smaller boiler unit may be adopted with, again, a gain from stand-by losses.

On the other side must be put the cost of water for condensing, the cost of circulating it and cooling it, and charges on condensing plant and addition to engine. In this connection it is well to note that a saving is affected in boilers, a plant with heavy rate of depreciation, repairs, and up-keep, and an addition is made to capital account on which the charges for depreciation and repairs and up-keep would be almost negligible. Each case must be decided on its merits when the local conditions are known. I may add that this statement follows from Mr. Willans' straight-line curve of total steam consumption. (*Proc.Inst.C.E.*, Vol. CVI., p. 62.)—Yours, &c.,

Reginald Wood.

A letter from Mr. S. Mavor in answer to Mr. S. F. Walker has come to hand too late for insertion in this issue.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1893 Edition of "The Electrician" Electrical Trades' Directory and Handbook is now ready. This useful book contains over 1,000 pages, and several new and handy features have been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

Tenders Invited.—The Postmaster-General invites tenders for the purchase of about 26 tons of gutta-percha in various forms (principally in strippings), about 60 tons of copper (principally wire), and quantities of zinc and other metals, &c. Some further particulars will be found in our advertisement pages, and all necessary information may be obtained on application (by letter only) to Mr. Chas. E. Stuart, Controller of Stores, Telegraph-street, London, E.C. Tenders have to be in by the 25th inst.

——— The Town Council of Aberdeen invite tenders for various work under their Electric Lighting Order. Further particulars are given in our advertisement columns, and full specifications and drawings can be had either from the Town Clerk, Aberdeen, or from Prof. A. B. W. Kennedy, 19, Little Queen-street, Westminster, London, S.W. Tenders have to be in not later than 10 a.m. on Friday, April 28th.

——— The Bedford Urban Sanitary Authority, it will be seen by our advertisement columns, invite applications from companies or firms willing to undertake and carry out the powers granted them under their Provisional Order. Applications must reach Mr. T. S. Porter, the clerk to the Urban Sanitary Authority, on or before May 13th.

——— The General Direction of the Posts and Telegraphs in Madrid is inviting tenders until the 24th inst. for the establishment and operation of a telephone exchange in the town of Haro, in the province of Logrono, Spain.

Tenders Accepted.—The Great Northern Railway Company have accepted the tender of the Brush Electrical Engineering Company for the supply and erection of alternators and arc dynamo machines for the large station to be put down at Holloway for lighting a number of the Company's stations up and down the line.

——— In reference to the acceptance of the tender of Messrs. Siemens Bros. and Co. for supplying and laying the whole of the electric conductors for the Whitehaven installation (which appeared in our last issue), the total sum of the tender is £4,014. Messrs. Siemens' tender has been finally accepted.

For Disposal.—Mr. R. L. Impey, chartered accountant, of 26, Waterloo-street, Birmingham, is open to receive offers for the purchase of the business plant, &c., of Fowler, Lancaster and Company (Limited), (in Chancery).

——— Mr. Impey also invites offers for the purchase of the business plant, tools, &c., Birmingham Telegraph Factory (in Chancery).

——— The liquidator of the Automatic Standard Screw Company (Limited), of Halifax, invites offers for the business as a going concern, with machinery, plant, tools, &c. The Company is engaged in the manufacture of a variety of high-class screws, fancy turned metal, &c.

Bankruptcy.—In the matter of Austin Herbert, recently trading as an electrician at St. James's-street, Nottingham, recently adjudicated a bankrupt, the liabilities amount to £172, and the assets are estimated at £55.

Legal.—An action brought by Mr. R. Lawrance, of Liskeard, against Mrs. Mary Knight, of Torquay, to recover certain sums for fixing electric bells, telephonic communication, &c., was on Monday last dismissed in favour of the defendant with costs against the plaintiff.

Change of Address.—The address of Mr. James Swinburne, consulting engineer, is now 4, Hatherley-road, Kew Gardens, Kew.

Earl's Court Exhibition.—The Brush Electrical Engineering Company have contracted for the supply of the electric generating plant required for the electric lighting of the Gardening and Forestry Exhibition to be held at Earl's Court this year.

Messrs. Drake and Gorham.—During the Easter holidays this firm removed and reinstalled the extensive electric light plant of the London and River Plate Bank without inconvenience to the bank officials. The plant was originally put down six years ago. The new bank premises have been fitted with an electric lift, which will be worked by the accumulators used in the lighting. The new

Hosted by Google

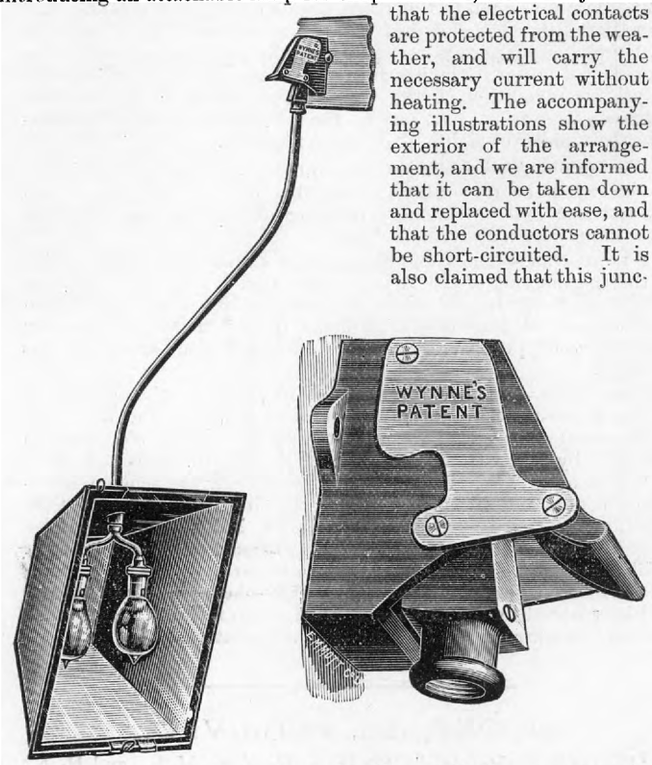
lift is similar to those originally put in the old premises, and which has been at work for years without costing anything for repairs.

J. E. H. Gordon and Co. (Limited).—An advertisement requests trade creditors of this Company (in liquidation) to communicate with Mr. Henry F. Kite, solicitor, 11, Queen Victoria-street, E.C.

Messrs. Coupier and Drouart.—Those in search of artistic statuettes and reproductions will find on show at this firm's premises at 75, High Holborn, London, W.C., a very choice variety of examples in the highest style of art. The firm are well in touch with the requirements of the trade, and their show-rooms will repay a visit.

The Priestman Oil Engine.—Messrs. Priestman Brothers (Limited) report a steady progress in the sale of this engine, and that, in order to meet the demand, a large addition to their shops and plant has been made, enabling them to reduce the cost of production. The firm are now in a position to make a reduction in the prices of their oil engines, without in any way lowering the quality of the workmanship or material hitherto supplied; and to all engines of 5 H.P. and upwards a new patent self-starter is fixed free of charge. A new price list is issued, and can be obtained on application at the Hull, London, Glasgow or Melbourne offices of the Company.

Shop Window Lantern.—Messrs. Wynne and Barnard are introducing an attachable lamp for shop windows, &c. They claim that the electrical contacts are protected from the weather, and will carry the necessary current without heating. The accompanying illustrations show the exterior of the arrangement, and we are informed that it can be taken down and replaced with ease, and that the conductors cannot be short-circuited. It is also claimed that this junction can be applied for railway signalling and other purposes, including the lighting of picture galleries, for which purpose the lamps are made in ornamental designs.



Telephone Transmitters.—The National Telephone Company have for some weeks past been experimenting upon various forms of transmitters and with the latest inventions and modifications of these instruments, in view of selecting the best form for use with their telephones. We understand that the Company do not contemplate superseding the Blake transmitter, but are anxious to secure for their subscribers the most efficient form of transmitter in the market.

The "Victor" Turbine.—Mr. F. Nell sends us a well-illustrated pamphlet of illustrations and particulars of the "Victor" turbine water-wheel, from which particulars may be obtained of a variety of purposes to which these water-wheels have been in the past, and are being, applied. Tables of power, speed, head of water, and cubic feet discharged are given, together with instructions for measuring water-power, construction of head races, &c. Illustrations show the setting of turbines for high falls, &c., and testimonials from users are also included.

Messrs. Hampton and Sons' Catalogue.—The claim of Messrs. Hampton and Sons' that their new catalogue and book of designs surpasses anything of the kind yet produced cannot be gainsaid. We are accustomed to the finest printing and elaborate get-up in electrical catalogues, but Messrs. Hampton and Sons have put every other list in the shade, not only in the photographic collotype illustrations, but in the handsome embossed binding. A special electric light department has been opened by this firm, and we find lamps, switches, and ceiling roses, as well as a number of designs for fittings. Messrs. Hampton and Sons seem to have succeeded where so many others have failed, in offering some graceful but simple wall-brackets.

Aberystwith.—Prof. Garnett has furnished the Town Council with a lengthy report on their electric lighting schemes, which is to be printed in full and circulated amongst the members. Prof. Garnett has reported upon three possible schemes, discarding the one by which the town refuse is to be utilised. We understand the lowest estimate is £11,000, and several members of the Town Council were of opinion that this was too large an amount to be expended at the present time. It was, therefore, resolved to ask the Public Lights Committee to present a smaller scheme for the Terrace and some of the principal streets. The opinion was freely expressed that the desirability of the light was beyond question, an experimental installation having given the greatest satisfaction. The subject will again come up for discussion at an early meeting of the Town Council.

Belfast.—A meeting of the Town Council was held on Tuesday last to take into consideration the report of Prof. Kennedy relative to the introduction of the electric light into Belfast. A full abstract of this report appeared in *The Electrician* of March 10th last, and the scheme for the lighting of the central, or compulsory, area at an estimated cost of from £19,000 to £20,000 was, adopted by the Council. The Gas Committee was authorised to carry the recommendations into effect forthwith. It will be seen from Prof. Kennedy's report referred to above, that the plant proposed to be put down in the estimate would be sufficient to keep 6,100 lamps alight simultaneously, with sufficient reserve for a total estimated supply to 8,500 lamps in all.

Blackpool.—The residents in the North Shore complain that the electric lighting installation has not been extended to that district. The Electric Lighting Committee have the matter under consideration.

Bombay.—The Municipal Council Chamber and offices have been fitted throughout with the electric light, under the supervision of Mr. P. Mossop, of the Laing, Wharton and Down Construction Syndicate (Limited), whose agents, Messrs. Richardson and Cruddas, have had the contract in hand. There are between 350 and 400 lights.

Bowness.—The Police Commissioners have appointed a Committee to inquire into the practicability of utilising water-power from the River Avon for the purpose of lighting the district by electricity.

Burnley.—The Electric Lighting Committee have decided that the price for the supply of current for electric lighting purposes, be fixed at 6d. per unit, and that the rent for meters be 10 per cent. the first cost to the Corporation.

Chelmsford.—The large Pantechnicon, No. 2, which Messrs. Wenley and Sons have erected in New-street, has been fitted throughout with the electric light. The old building, No. 1, has also been similarly fitted.

Church Lighting.—A correspondent of the *Yorkshire Post* appeals warmly to the parishioners of Leeds for the sum required to instal the electric light in the parish church, on the plea that "the best of everything should be found in the house of God." A meeting was held last week, and the proposal to adopt electric lighting was strongly approved by the vicar.

Dundee.—A statement has been prepared by which it is shown that the electric lighting scheme entails a gross expenditure of £28,030, including the cost of the Provisional Order. The Gas Commission have power to borrow to the extent of £20,000, and it has been resolved to borrow a further £10,000 in order to meet any slight additions that may be necessary. Applications for the light are very encouraging.

Halifax.—The Gas Works Committee have resolved that the proposed purchase of the plant of the Halifax Mutual Electric Light and Power Company (Limited) be not entertained, but that the Company be asked for permission for an inspection of their books to be made, and to state whether they are prepared to continue the supply of light until the Corporation's works are ready, the Corporation paying a consideration under such an arrangement. The Council have approved the action of the Committee. The engineer to the Council has presented his report, and it is intended to have plans prepared and tenders obtained with the view to carrying out the engineer's recommendations on the subject of lighting the Borough.

Hastings.—We understand that the contract between the Town Council and the Hastings Electric Light Company for the lighting of the whole of sea-front line has been completed.

Hosted by Google

HEREFORDSHIRE.—A meeting of the Joint Committee of the Quarter Sessions was held last week, and the subject of lighting the Shire Hall was discussed. Sir Herbert Croft strongly advised the introduction of the electric light throughout the Nisi Prius and other courts. Sir Richard Harrington, in reply, stated that the County Surveyor (Mr. Wakelam) would be asked to consider how best the Court could be lighted and at what cost. He agreed that the electric light would be much preferable to gas, but the cost would have to be considered, as the installation would be an isolated one.

ISLINGTON (LONDON, N.).—The Electric Lighting Committee of the Vestry has had under consideration a communication from Messrs. Sharp and Kent, offering to sell to the Vestry at any time within two years the whole of their property, lands, leases, machinery, and mains in the parish, for the amount expended upon them, plus a fair profit, on condition that the Vestry gives its consent to their application for a Provisional Order. The Committee recommended that the proposal be not entertained, and their report has been adopted.

LEEDS.—Several members of the City Council are desirous of removing the engines and dynamos used in the municipal buildings installation, and taking their supply from the public lighting mains. In all about 3,000 lamps are used in the Corporation buildings, and the Yorkshire House-to-House Electricity Company have notified the Council that they are not in a position to supply so many lamps from their mains.

LECTURES.—Electricity, or some of its varied applications, has formed the topic of lectures delivered respectively by Mr. Crompton at Hove, Mr. Watkinson at Sheffield, Mr. Headworth at Poplar, Mr. Anderson at Caithness, and Mr. J. Ritchie at Edinburgh.

LIGHTING OF TOWER CLOCKS.—The tower of the Bradford Town Hall is furnished with a clock of which the citizens are proud, and some time back agreed to an expenditure of no less than £800 per annum in lighting the clock by electricity. The Lighting Committee of the Corporation have recently been experimenting with the object of reducing the cost, with the result that at the present time it is estimated that the annual cost of lighting the clock will be reduced to £137, which is about £70 less than the cost of lighting it by gas.

LLANGOLLEN.—Mr. Davies, a member of the Local Board, has brought the subject of lighting the district by electricity prominently forward, but at the last meeting, after some discussion, it was resolved to defer the consideration of the matter for a month.

MIDDLESBOROUGH.—The Electric Lighting Committee of the Town Council have appointed a Sub-Committee to obtain information as to the cost of lighting the municipal buildings by electricity, and for providing arc lamps for the exterior lighting.

MONTROSE.—The Police Commissioners have appointed a Committee to consider the advisability of having the town lighted by electricity. It is probable that water-power will be used.

OXFORD.—The Oxford Electric Light Company have agreed to supply current to the Carfax clock free of charge during the continuance of their contract with the Corporation for street lighting.

PARTICK.—A Bill confirming the Provisional Order by the Board of Trade for the electric lighting of Partick has been issued.

ROMSEY.—It is stated that Romsey Abbey is to be lighted by electricity during the current year.

ROTHESAY.—The Joint Committees of the Harbour Trust and Town Council have decided to defer for the present the consideration of the adoption of the electric light for the harbour and esplanades.

RUGBY.—It has been decided to adopt the electric light for Rugby School. The installation will consist of about 750 16-c.p. lamps and 750 8-c.p. lamps for the various schools, boarding-houses, and other buildings. Mr. J. A. McMullen has been appointed consulting engineer to the scheme, which will be carried out during the ensuing term and the August vacation.

SCARBOROUGH.—The report prepared by Mr. Bernard Drake has been submitted to the Electric Lighting Committee of the Town Council and approved, with the addition that the mains be laid throughout the route selected by the Scarborough Electric Supply Company as near to the houses as possible.

TAUNTON.—The National Telephone Company are contemplating opening an exchange at Taunton, with subscribers at £9 per annum.

THEFT.—At the Salford Borough Police Court on Saturday last, John Pollitt was charged with stealing electric bells, coils of wire and other articles, from the works of the General Electric Company, at Clegg's-court, Chapel-street, Salford. A quantity of goods had been stolen from the works, and suspicion fell upon the prisoner, and a man named Charles Woodward was charged with receiving the goods so stolen. Pollitt was fined 40s. or fourteen days imprisonment, and Woodward was liberated on his own recognisances to come up for judgment when called upon.—— Percy Gordon Glynn, described as an electrician, was sentenced to three months' imprisonment at the Northamptonshire Quarter Sessions, for stealing a bicycle.

TIVERTON.—Mr. Siddalls, the surveyor to the Town Council, has presented his scheme for lighting Tiverton by electricity. A Provisional Order was obtained in 1890, but efforts to transfer the powers under the Order to other persons have proved unsuccessful. Mr. Siddalls has, therefore, prepared an estimate of the probable cost of the work if the Council undertake their own lighting, recommending the use of the high-pressure alternating-current system. He also recommends the use of water-power, which it would, in his opinion, not be difficult to obtain. Two estimates were submitted. Under one estimate (using water-power) the capital outlay is put down as £13,740, and maintenance, including interest, &c., at £1,700 per annum; using steam-power, capital outlay £10,170, maintenance £2,349 per annum. The second estimate embraces a more extensive scheme, and includes 4,000 private lights, the capital outlay for which is estimated at £17,080, by water-power and by steam £12,640, with an annual cost of maintenance in the first case of £2,050, and in the second of £2,842. Mr. Siddalls estimates that with water-power a revenue may reasonably be expected of £1,800 per annum in the first estimate; in the second estimate, £2,800 per annum.

TUNBRIDGE WELLS.—The report of the Electric Lighting Committee was presented to the Town Council at the last meeting, and was approved. The Board of Trade had informed the Committee that they had no powers for extending the period stipulated in the Provisional Order for laying down the mains, but were prepared to defer the revocation of the Order for a period of six months. Circulars were to be sent out to the inhabitants in order to ascertain the number of lights likely to be required.

WATFORD.—After discussing the question of the introduction of the electric light at Watford, a member of the Local Board has given notice that at the next meeting he will propose that the Board apply for a Provisional Order.

WINCHESTER.—The General Purposes Committee recommended at the last meeting of the Town Council that a sum not exceeding £60 be spent for inquiries into the cost of electric lighting for the district, and the feasibility of utilising the water-power at the city mill for that purpose. The Committee's recommendation was adopted.

WORCESTER.—A local Government inquiry into the application of the Worcester Corporation for powers to spend the necessary money on their electric light undertaking was held at Worcester on April 6th by Major-General Crozier, R.E. Mr. W. Geipel attended on behalf of Mr. W. H. Preece and explained the scheme, afterwards conducting the inspector over the site acquired by the Corporation for the central station, Penrith Mills, about two miles from the city. It is estimated that the maximum water power available at the fall is 1,500 H.P., and turbines for upwards of 600 H.P. are to be at once erected. This scheme, as it progresses, will be watched by the profession with much interest. It is anticipated that current will be supplied early next year.

COMPANIES' MEETINGS & REPORTS.

City of London Electric Lighting Company (Limited).

The third ordinary general meeting of this Company was held at Winchester House, Old Broad-street, yesterday, under the presidency of Sir David L. Salomons, Bart.

The SECRETARY (Mr. J. Cecil Bull) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said: Every meeting of this Company I regard as adding a fresh chapter to the history of the lighting of the City by means of electric energy. It is, after all, nothing more or less than a series of events that form a history, which no doubt will be remarkable in its way when we get to a conclusion of it, as has been the history of the companies that have gone before it. In the case of the London Company you have a history which we have made use of, as other companies have done. That Company has paid penalties in creating its history which we shall try to avoid, but I have no doubt that we shall make errors, which cannot be avoided in dealing with a new state of things. We intend to put before our shareholders, not only in this room, but to those who are absent, the position of our affairs, and we shall furnish a report in which we shall give them all the information in our power. I do not believe in making mystery when it does not exist. There are always negotiations going on in companies which it is not wise to divulge until they are concluded. You have that in your private business just as much as in companies, but it is our desire that you should know everything possible that is being done. At the last meeting a set of accounts was issued which was criticised, though I will not say adversely. They were, however, only incomplete accounts, but still they gave you a general knowledge of what was being done with your money. The Board of Trade have certain forms which they require to be filled up at the end of every year to December 31st, and the accounts which we present in accordance with the form prescribed by the Board of Trade you have just taken as read. I do not know if the form could be improved or not, but it is the form prescribed by Act of Parliament. I think that, taking it all round, the form is understood by the majority of people. I am now going to make a few remarks which will give you the history and position of the Company up to to-day, as far as that can be done. A report can never contain what you can say in a few words. Before proceeding with these remarks I must express our great regret that we have lost a valued colleague, one who took the greatest interest in this Company, not only in the Board room but also outside. I refer to the late Duke of Marlborough. I expressed our regret on the last occasion that Mr. Charteris, one of our Directors, was then absent, and I regret to say that he is still an invalid, but we hope he will be amongst us again soon. Mr. Charteris has served his country well under arms, and I am sure you will agree with us in extending his leave of absence. Two of our Directors retire. They have to do so by rotation, and the two gentlemen who have offered to retire are Mr. Braithwaite and Mr. Reynolds. They have rendered such valuable services to the company that you will be asked, by-and-by, to place them on the Board again, as they are eligible for re-election. Mr. Braithwaite is now Chairman of the Brush Company. The fact that he is a Director of that company might, in the sight of many be considered a disadvantage in connection with his being on this Board as well ("no, no"). I did feel a little before the Company started that it would be disadvantageous for a gentleman who was connected with the contractors to be on the Board of this Company, but I have altered my opinion completely since then, for I have found that they have served your interests most faithfully, and the contractors are tied down in their agreements to us. As regards the officers, including the engineer and manager, our secretary, the engineer of buildings, and numerous other members of our staff, I cannot say more than this—that they have have worked extremely hard to promote your interests—much more than could have been expected from them for the pay they have received or that may be accorded them in the future. Statistics are very dry, I known, but at the same time I am going to trouble you with a few figures. When they appear in print you will have an opportunity of studying them and comparing them, and thus of seeing how far the Company has progressed or whether it has gone back. In the half-year ended December 31st last £96,000 was expended on capital account, made up as follows: Machinery and plant £16,070. The plant in position at December 31st last was sufficient in boiler power for 63,000 8-c.p. lamps, in engines and dynamos for 37,500 8-c.p. lamps, and in transformers for 36,000 8-c.p. lamps, with all necessary accessories. On conduits and re-paving (including £17,268 for telephone tubes) £34,044 was expended in the half-year; while on cables, house services, meters and sundry expenses the outlay was £16,900. The work carried out in connection with the last-mentioned sum includes 183,686 yards of ways laid in 24,810 yards of trench, and the cables reach a total of 32,455 yards high-tension and 24,633 yards low-tension. The public lighting absorbed £8,176; tools and plant £298, office furniture £245, management and general expenses £1,037, and on land and buildings the outlay was £19,169. This makes the total expenditure £95,939. That was to the end of last year. On April 12th we stood thus: Total ways laid by the Company, 427 miles; cable drawn high-tension 60½ miles, and low-tension 35½ miles. The number of lamps applied for during the six months ended December 31st last was 21,000 8-c.p., and the number connected up during that period was about 8,400. The additional plant which is now down has enabled the Company to connect 18,000 lamps since the beginning of this year, a result which is very satisfactory. The total number now supplied from the Company's mains is 38,200. It must be borne in mind that the supply of current until now has been a source of great anxiety. The demand has been continuous, and we are still running off the pioneer stations which the Company took over when it was formed. In order, however, to get over some of our difficulties we have ordered, and are now running, two large half-units, each of which supplies over 6,000 8-c.p. lamps—that is, between 12,000 and 14,000 extra 8-c.p. lamps can be supplied more than when the pioneer station was running by itself. These are now assisting that station, and have removed a great deal of trouble with which we had to contend. Everyone was grumbling because he was not put on first, but that state of things is sobering down gradually. These half-units are driven by ropes, but the permanent machines will be worked by direct ribbon. The Board have made a contract with the Brush Company, to the effect that when these two machines are not required any more they can be taken out, and they will be replaced by direct-ribbon machines. There are some very large units on order now from the Brush Company and from the Laing, Wharton and Down Syndicate. Of the two first great units in course of construction by the Brush Company, the first one is completed, and has been tested at the works by the contractors. The final results are not yet known to us, but it ran very well as far as could be judged at the time. In about six weeks this large unit will be running at our station, or ready to run. The second and third units are well advanced in their manufacture. These machines will each give a current to supply about 14,000 8-c.p. lamps. The Laing, Wharton, and Down Syndicate are to supply two large units, which I understand are now ready in America. They have been made there, and that accounts for some delay, but we hope shortly to have them landed at our works on the Thames. We are making every endeavour, so that by the end of the year we shall be able to supply 130,000 8-c.p. lamps, if not more. I think that the great difficulties have been got over in this Company. After mature consideration, the Board came to the opinion that it would be desirable to give up the station at Wool Quay. It would have been a very expensive station to construct, and we should have had to incur considerable expense in keeping the place dry. There were, in fact, great risks and expenditure to be faced in continuing that station, and it would also be inconvenient, and certainly not economical, to have a double staff—one at Bankside and the other at Wool Quay. We therefore came to the conclusion that it was more economical to have this station by the side of the existing station at Bankside. The buildings are being erected in sections, so that one section after another may be built as the demand upon us increases. It is no use building up a great station some four times larger than you require, and it would be loading your capital if we did so. It is much better to go on meeting the demands gradually. A number of the new wires do not meet the specification required, and, as you know, a great many hesitate putting in the electric light until they see what the experience of their neighbours is. I have no doubt, however, that in another year the results shown will surprise many of you, judging what has taken place at the West End and in the rest of London. One section of our building is practically completed and partly in use, and another section will very shortly be finished. There are a few diagrams on the wall, and I desire to call your attention to one of them in particular. We requested our engineer and manager to draw up a area diagram showing graphically how our capital was divided up. Such a diagram tells you more than the most elaborate and eloquent speech or the most carefully audited accounts, for you have the whole concern under your eye at a glance. You will observe two area diagrams: both illustrate the same point, but they are drawn upon a different plan. In the one, the oblong is divided up into partitions, and in the other, every partition is made with an equal base. Some gentlemen are accustomed to one kind of diagram and some to the other, and in order to meet the two cases it was thought desirable to give two representations of the same thing. The Chairman then pointed out the chief features to be learned by an inspection of the diagrams, adding: The whole of the area represents our capital authorised of £1,200,000. A large margin is left for the purchase of land, buildings, plant, machinery, and transformers. On the other hand, you will observe that nearly the whole of the estimated expenditure for placing conduits under the streets has been made. In other words, we shall shortly be in a position to supply every place in the City, and I hope in Southwark also, but the latter district is a very small affair. We hope, however, before long to have Southwark in the same condition as the City, but we only got the Provisional Order for that comparatively recently. Of the cabling to be done a large amount remains. This, however, is only natural, as the cables will be drawn into the conduits as the demand requires, a very short space of time being necessary for this operation. The same remarks apply equally to the meter service, &c. The lamp-posts in the streets, with a few exceptions, are completed. As regards the lesser streets, there is a difference in the contract as between the main thoroughfares, which are now practically completed. The difference is that in the main thoroughfares the lighting is by the arc system, and the lesser streets it was proposed should be lighted by incandescent lamps. We were to light the main street straight away, but as regards the lesser streets we had to wait until we received orders to light them. At the present moment two of the lesser streets are being prepared for the City Commissioners to see, and if they approve of the lighting we hope to get authority to proceed with these streets. I would like now to say a few words with respect to telephone tubes. This is a question of great importance to all London, and a great deal has been said in the papers on the subject from time to time. When the Company was formed, power existed for laying any number of spare tubes—we could lay as many as we wished. The Company knew at that time that Parliament would shortly be asked to give facilities for the laying of telephone tubes underground, and the Board were rightly informed in this respect, because a very short time after that—last year—an Act came into force enabling the electric lighting companies to lay tubes for telephone companies or to lease spare tubes they might have. The Directors were too well aware of the enormous inconvenience which the public must suffer during the time the trenches are open in the street, the traffic being impeded, and foot passengers being obliged to take to the road. In fact, no one blesses the Electric Lighting Company when they are operating in the

Hosted by Google

streets. You have only to picture to yourselves what would occur if, after pulling up the streets for our purposes, they had to be pulled up a second time. We hesitated to take such a responsibility, and we therefore laid in a very large number of spare tubes, believing that they would be required in a very short time. They were laid in not only with the desire to spare the City a great deal of trouble in the future, but they were laid in also with the knowledge of the City Commissioners. When the Act of Parliament was passed it became necessary to see if we could not utilise these spare cables. We had a provisional or informal agreement with the New Telephone Company with regard to these tubes. The agreement could be completed for their use to draw in the twin wires, but this could not be done without the consent of the City Commissioners, the Post Office, and the Board of Trade. So far, we have failed to get the consent of the City Commissioners, and I regret this very much. The whole of the lighting of the City has been done in a satisfactory manner, and at all events there has not been much to complain of, and if our temporary arrangements are so good, I think that the permanent ones which will shortly come into play will enable us to beat the other companies, or, at all events, to be equal to the best of them. Any income that may be derived from these telephone tubes will not go into the shareholders' pockets directly, though, no doubt, it will do so indirectly; but it will assist in bringing the sliding scale for the price of current into force at an earlier date. Your Board would not be true to their trust if they attempted to lower the price of the current in the City before they saw that your interests would be secured, and any facilities which the City Commissioners may give us to make the Company a success and allow us to reduce the price, will not only be benefiting you as shareholders (which, after all, is not their business), but the very people they look after in the City. As regards the telephone tubes again, there exists now underground a complete system, and they have been laid at a price very much lower than could have been done had we waited until we were asked to put them in, for the reason that when the trenches were open all the tubes were put in at once. This saved a great deal of expense and avoided a very considerable amount of inconvenience to the traffic. There is a complete system now underground, as I have said, which will enable a most efficient telephone service to be given. I trust that the time will not be long distant before the City Commissioners may say that these tubes may be used. Meantime, they may not be aware that the overhead wires are being doubled—a proceeding greatly to the disgrace of London and the danger of the public, and if it goes on as in the early days of electric lighting there will be a great outcry, great expenditure, and a vast amount of inconvenience. Although the Commissioners have not met us on this particular point, they have given us facilities which in other ways have enabled us to supply the current to the satisfaction of most of our customers, and for this we are very grateful to them. There are some persons who imagine that our Board have been very slow in getting on with this work. It will, however, be two years next August when this Company first came into existence. Now, the first six or eight months is practically lost by a company in settling plans, but since then very great progress has been made, as you see by the plans and diagrams here. As regards the permanent machinery, special machinery had to be made and put down. This is now all done, the plant is all down, and these big machines are being turned out as rapidly as could be expected. There has been a good deal of difficulty in purchasing a large number of small bits of land, and this has caused delay. Besides all this we have had the London County Council, the City Commissioners, Local Authorities and others to deal with, but one delay after another has been got over. It is suggested by your Directors that since the Board of Trade requires a special form of accounts to be delivered once a year—to December 31st—it will be convenient for the Company to issue their accounts yearly in accordance with this form. We propose to adhere, therefore, to this form in the future, and to hold half-yearly meetings in order that you may know what is going on. A great deal takes place in this Company in the first six months of the year, and you will like to have half-yearly meetings to know the progress that has been made. At that half-yearly meeting, however, there would be no accounts issued, as that would entail a great deal of work and it would not be satisfactory to you. We propose, therefore, to issue the accounts in full in accordance with the Board of Trade form, as on the present occasion, and to hold half-yearly meetings as soon as possible after January and July, if we cannot do so in those months. These are all the remarks which I have to offer beyond any information that I can give you afterwards in reply to questions. I now beg to move—

"*That the Directors' report and statement of account and balance-sheet to the 31st of December, 1892, be, and the same are hereby, received and adopted.*"

Mr. J. B. BRAITHWAITE, jun., in seconding the motion, said that the progress which they had made, in view of all the circumstances which the Chairman had brought before them, could hardly fail to be satisfactory to them. When it was considered that in undertaking the electric lighting of the City of London they were undertaking, probably, the largest task of the kind ever undertaken by a private company.

In answer to Mr. CUTCLIFF, the CHAIRMAN said that each lamp had earned practically 14s. a year, so far. The average number of lamps connected in the six months ended December 31st last was 15,000.

Mr. GEORGE HERRING said he thought that the reference by the Chairman to the source of revenue they had in the telephone might be misunderstood. The Chairman stated that this revenue would not go directly into the pockets of the shareholders. He (the speaker) concluded by that that this revenue would only help in the future lowering of the price per unit.

The CHAIRMAN, in answer to other questions, stated that the contract with the City was for 21 years, but it could be terminated in 7 years. It did not at all follow that because there was a loss now on the public lighting there would always be a loss on it. They lost at the outset on the private lighting.

The resolution was then carried unanimously.

On the motion of the CHAIRMAN, seconded by the Earl of SUFFOLK and BERKSHIRE, and supported by Mr. B. H. VAN TROMP, the retiring Directors were re-elected, as were also the auditors, Messrs. W. H. Pannell and Co.

The CHAIRMAN, in answer to a further question, stated that the presentation of half-yearly accounts would cause many difficulties, but figures would be given at such meetings, and there was nothing to prevent the declaration of half-yearly dividends.

Mr. HERRING then proposed a vote of thanks to the Chairman and Directors. He pointed out that it was very easy to pass such a vote when Directors paid good dividends, but he reminded them that Directors really had more work to do when a company was not earning dividends. He, therefore, thought that the Directors should be all the more warmly thanked for the work they had done, and what they still had to do. He did not think it was thoroughly understood that from January 1st the Company had been earning a fair and good profit, and when they considered that that was upon an average of from 20,000 to 25,000 lamps, and that they hoped eventually to supply nearly 400,000 lamps, he did not think the shareholders need have much doubt of their future. Then, they had not been benefited in the half-year by the revenue to be obtained from the telephone tubes; and as regarded the public lighting, they need not anticipate the continuance of loss. He might also point out that in connection with each of the public lights, a great part of the work that was done would have to be done for the private lighting. The loss, therefore, was not so absolute as might appear.

Mr. JOHN NEWTON seconded the motion, which was carried unanimously.

The CHAIRMAN, in acknowleding the vote, said that he never liked to state anything that might lead to speculation, but if he had desired to do so, he could have made statements which would have made things look very much more *couleur de rose*. He added that every pound that would now be spent would bring in revenue.

The proceedings then terminated.

Metropolitan Electric Supply Company (Limited).

The following is the report of the Directors, to be presented to the sixth ordinary general meeting, to be held at Winchester House, E.C., on Friday next, the 21st inst., at 12 o'clock:—

The capital expenditure, which at the end of 1891 amounted to £486,926, now stands at £550,859. 16s. 11d. This increase is chiefly due to the laying of additional mains, and to the works in connection with the new station at Paddington, which, it will be remembered, was not contemplated in the original estimates. For the purpose of completing the Company's present system it will be necessary to issue the balance (£50,000) of the £100,000 debentures already authorised.

The gross revenue for the year amounted to £54,571. 19s., as against £43,747. 1s. 3d. in 1891, or an increase of £10,824. 17s. 9d. It will, however, be remembered that the revenue of that year included a special item of £3,027. 1s. 3d. paid by the contractors. The actual increase, therefore, amounts to £13,851. 19s.

The balance to the credit of the revenue account, before providing for depreciation, is £18,168. 1s. 1d. The Directors have set aside £4,000 as a Depreciation Fund, carrying to the credit of the net revenue account the sum of £14,168. 1s. 1d. which, with the balance brought forward from the last account, and other receipts, makes a total of £15,144 11s. 3d. After deducting bank charges, debenture interest, &c., there remains a balance of £12,558. 18s. 1d., of which the Directors have appropriated £1,000 in reduction of the preliminary expenses account, which will now stand at £4,052. 10s. 4d.

The Directors recommend that a dividend of 4s. per share be now paid, which will absorb a sum of £9,980, carrying forward the balance of £1,578. 18s. 1d. to the next account.

A comparison of the present revenue account with that for 1891, will show that the Directors' anticipations as to the increase in percentage of net profit are being fulfilled, and they look forward with confidence to a continuous increase in the proportion of net profit to gross revenue in the future.

The number of 8 c.p. lamps supplied by the Company, which at the end of 1891 was 82,000, increased during the year 1892 to 124,000. The number at the present date amounts to 134,453. It will be noticed that the rate of increase is constant, and the applications continue to show steady progress.

The generating station at Paddington is completed, and in regular and satisfactory operation. A report from the Company's chief engineer to the effect that the stations, machinery and plant are in a satisfactory condition is attached to the Directors' report.

The Directors have appointed Sir Eyre Massey Shaw, K.C.B., to a seat on the Board. In accordance with the Articles of Association the following Directors, viz.:—Sir John Pender, G.C.M.G., M.P., Sir James Anderson, and Sir George Elliot, Bart., retire from the Board, and, being eligible, offer themselves for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths and Co., retire, and offer themselves for re-election.

The Telephone Company of Egypt (Limited).

The tenth ordinary annual general meeting of this Company was held on Tuesday, April 11th, at the offices of the Company, 14, Austin Friars, so that the Directors' report and the accounts for the year ended December 31, 1892, might be submitted, a dividend declared, and the ordinary business of the Company transacted.

General Alexander Fraser, C.B., R.E., the Chairman of the Company, presided.

Mr. ALEXANDER B. CHALMERS (the Secretary) read the notice calling the meeting.

Hosted by Google

The CHAIRMAN said: Well, gentlemen, as the report has been issued to all the shareholders, I presume you will take it as read. Well, gentlemen, I have not much to say to you beyond what is stated in the report, and I think there is no need to go into detail respecting the irregularities of the late representative of the Company at Cairo, beyond saying that Mr. Begni, the said representative, has disappeared from Egypt, and the Directors are consequently prevented from taking any criminal proceedings against him, and they feel bound to write off—as stated in the report—those losses. We then thought it necessary to depute our able secretary, Mr. Alexander B. Chalmers, to go to Egypt to inquire into matters connected with the irregularities, and with the consent of the chief shareholders he was employed there about a month, with the satisfactory result that, from his report, the Board has been able to put the management on what it hopes will be a safer basis by the introduction of new blood, in placing Mr. Evans our general manager at Cairo, which is now the seat of Government and is more promising in respect of extension of business than Alexandria now is, and by the introduction of certain safeguards in respect of the local control of the business by Mr. Chalmers. Then Mr. Chalmers also suggested certain improvements in the construction of the works at Cairo, which the Board has thought it well to adopt, and, on the whole, the Board is of opinion that the result of Mr. Chalmers's deputation to Egypt has been highly satisfactory, while through him the Board has been brought more directly in communication with its *employés* in Egypt. I do not think that I have anything more to say. I shall be glad to answer answer any questions that any shareholders may desire to ask, and I will now move:—

"*That the report and accounts for the year ended December 31, 1892, be, and are hereby, approved and adopted, and that a dividend of 6 per cent. be declared on the preferred shares, free of income tax.*"

Mr. THOMAS LLOYD: I beg to second that.

No questions were put, and the resolution was carried unanimously.

The CHAIRMAN proposed the re-election of Mr. Thos. Lloyd as a Director, which was seconded by Mr. HENRY GREWING, and carried unanimously.

The auditors, Messrs. Price, Waterhouse, and Co., were also re-elected, and a vote of thanks to the Chairman terminated the proceedings.

The following is the report of the Directors referred to above:—

The revenue account for the year ended December 31st last, shows a balance to credit of £4,079. 3s. 4d., after providing for interest on debentures; and including the amount of £1,414. 17s. brought forward from 1891, there is a balance for disposal of £5,494. 0s. 4d. This the Directors propose to deal with as follows:—To pay a dividend of 6 per cent. on the preferred shares, free of income tax; to appropriate £426 7s. 4d. in reduction of capital expenditure and depreciation of stores; and to carry forward £1,446. 7s.

The Directors regret to report serious irregularities on the part of the late agent at Cairo, who had been in the employment of the Company for about ten years. The losses consequently sustained, being in the opinion of the Directors irrecoverable, they decided to deal with the matter at once by writing them off; but for these losses, the result of the year's working would have been more favourable. The head-office of the Company in Egypt has since been removed from Alexandria to Cairo, with Mr. Evans in charge, and it is hoped that the other arrangements which have lately been carried out in connection with the management and control of the business will lead to increased prosperity.

The gross revenue of the Company on January 1st last was £12,225, and the total number of lines, exchange and private, 1,138. The increase of business for the first quarter of the current year has been fairly satisfactory.

Eastbourne Electric Light Company (Limited).

The annual general meeting of the shareholders of this Company was held at Eastbourne on Thursday last week, the Mayor (Alderman George Boulton, J.P.), who is Chairman of the Company, presiding.

The CHAIRMAN, in moving the adoption of the report (which appeared in our last issue), congratulated the shareholders upon the fact that the Company was progressing, and that the Directors could at last offer them a dividend on their shares—not a large one, but one they were likely to improve upon. The number of 10 c.p. lamps actually fixed was 7,667, and they had on order 353. The number of 10-c.p. lamps fixed last quarter was 623, the approximate value of the installation work done during that period being £605. They had a total of 10¼ miles of circuit. It was proposed to move in the direction of Upperton, whose residents wanted the electric light, but the expense would be about £6,000, to provide for which the Directors must, of course, obtain fresh capital. He would not go into details in regard to the future, but congratulated them on the dividend they were enabled to declare, and for which the shareholders had waited patiently 12 years.

Mr. J. G. LANGHAM, in seconding the motion, said that the Company was not instituted originally with a purely commercial motive, but with the hope of promoting the benefit of the town and advertising it effectually to the outside world. Commercial interests, although not foreign to the consideration of the shareholders, was certainly a secondary matter. Therefore they had none of them grumbled very much so long as they were effecting that primary object, the advance of Eastbourne, and they had been content to wait for a dividend until now. At the same time, the Directors could not forget the interests of the shareholders, and it was an immense satisfaction to find that, after sticking to the concern all these years, they had brought the Company to that state which allowed of a dividend being paid.

The motion having been carried unanimously, the Chairman was re-elected a Director, and the auditors were re-appointed; and £100 having been voted to the Directors for their services, the meeting closed with the usual complimentary resolutions.

Bournemouth and District Electric Supply Company (Limited).

The second annual general meeting of this Company was recently held at the offices, Bournemouth, under the presidency of Mr. Aymor H. Sanderson.

The CHAIRMAN, in moving the adoption of the report and accounts for the year ended December 31st, said that the Directors considered they had every reason to be well satisfied with the progress made by the Company during the past year, the result of the year's business showing a net profit of £327. 18s. 7d. The development of the Company's business was specially marked during the latter half of 1892, the larger portion of the 3,438 lamps added during the year to the Company's mains having been connected during that period. The number of lamps now connected was equivalent to 9,700 lamps of 8 c.p. Careful attention had been given to the details of the business, and the system of management had be enthoroughly overhauled and rearranged. It was hoped and believed that the station would be worked still more economically in the future, and would show further improvement as well as earn increased profits during the year 1893. Considerable additions and extensions had been made during the year to buildings, machinery, and plant at the lighting station. With regard to the issue lately made by the Company of £10,000 Six per Cent. First Mortgage Debentures, he was glad to inform the shareholders that £7,250 had been already applied for and allotted, and he had no doubt the remainder would be very soon taken up; these were actually mortgage debentures forming a first charge on the whole of the property of the Company, and they could not place any prior charge in front of them.

The Directors' report and accounts were then approved and adopted; and the retiring Directors and the auditors having been re-elected, the proceedings terminated.

Hastings and St. Leonards-on-Sea Electric Light Company (Limited).

The annual meeting of this Company was held on Friday, at Hastings, Mr. H. M. Baker presiding.

The CHAIRMAN, in giving a short retrospect of the history of the Company, said there was a time when they were opposed and laughed at; notice was given them by their bankers to pay off their mortgage; the Gas Company threatened to have a writ issued unless their unfortunate Chairman became personally responsible for the amount owing to them. Against all those things in the past, they now had the best public and private lighting business of any provincial town in England; they had got machinery which was second to none; they were one of the best customers of the Gas Company; they had reduced their mortgage from £4,000 to £3,000; and their bankers were pleased to take 4 per cent. interest instead of 5. Last, but not least, the Town Council were then confirming an agreement entered into by the Corporation with the Company for lighting the whole length of the front line with electricity. He alluded to the sad death of Mr. Mercer, their late manager, and said that while suggesting that £50 be voted towards the fund being raised for his widow and family, the Directors left the matter in the hands of the shareholders. He then moved the adoption of the report, which having been seconded, was carried, with the substitution of £75 for £50 for the Mercer fund.

The retiring Directors and the auditors having been re-elected the proceedings terminated.

The following is the Directors' report alluded to above:—

The Directors regret that some delay has taken place in issuing the report and balance-sheet for the past year, which is due to their having to wait for the accounts to be audited by the Board of Trade in accordance with the Provisional Order.

The sad death of the late engineer and manager (Mr. E. T. Mercer) is deeply regretted by the Directors, who had the highest opinion of the value of his services. He has left a widow and four young children unprovided for, and the Directors feeling that the shareholders would desire to recognise the valuable services rendered to the Company by the late Mr. Mercer propose to submit a resolution to vote the sum of £50 towards the fund being raised for the benefit of Mrs. Mercer and her family.

The past year has been one of steady progress in the prosperity of the Company, and the additional machinery which has been provided and which can be worked with greater economy of fuel, as well as the increase in the number of customers, must ensure satisfactory results in the future.

The accounts show that after paying all working expenses, and charging to that account repairs, interest on mortgage and debentures, there remains a net profit of £755. 8s. 2d., including the balance brought forward from the last account. The Directors propose to pay out of this sum a dividend of 5 per cent., which will absorb £569. 2s. 11d., leaving a balance of £186. 5s. 3d.

Messrs. F. J. Parsons and F. Noakes retire from the directorate by rotation; they are eligible, and offer themselves for re-election. The auditors, Messrs. Hart Brothers, Tibbetts, and Co., also retire, and offer themselves for re-election.

Elmore's Patent Copper Depositing Company (Limited).

An extraordinary general meeting of this Company was held on Friday, at Cannon-street Hotel, E.C., to receive the report of the shareholders' Committee appointed on the 16th ult., and to take such action thereon as might be deemed advisable. Mr. J. J. Atkinson presided.

Mr. TODHUNTER (the Chairman of the Committee) stated that they had received every assistance from the Board and managers of the works in investigating the Company's affairs. They had investigated the affairs of the Company so that no part of its past career had been passed over. The Committee's report is as follows :—

We find that the promoters took the lion's share of the money paid for the purchase of patents, &c. ; that the vendors' shares were divided practically between the present Directors (excepting Messrs. Hooley and Johnson) ; that, in fact, the Messrs. Elmore have received only a very small proportion of the purchase price, either in money or shares. We find that the sale of the licence to the Wire Company gave a net sum of £103,675. 10s. 9d. to this Company, of which only £20,000 was written off the original purchase money, and £70,000 divided in a dividend of 50 per cent., the then Directors taking a sum of £3,930. 13s. 1d. as their share of the profit. (Altogether the Directors have been paid £9,182 2s. 11d.) We consider that it was most imprudent and suicidal to distribute this large sum, which, in our opinion, was wrongly credited to income. We find that the Company in 1890 entered upon a land speculation, purchasing Haigh Park for £67,887. 16s. 8d. This transaction has helped, naturally, to hamper the finances of the Company. We find also that £11,938. 9s. was expended in the market purchase of shares in the Wire Company, presumably to bolster up the market, and that this is treated as a good asset in the balance-sheet, although the shares cost about £4 each.

We find that the defects in the engines, the leakage in the tanks, and the difficulties with the iron mandrels were the main causes of delay in the manufacture.

The Committee find that there are present liabilities of £7,327. 14s. 3d., besides a mortgage of £35,000 on the land, and a contingent liability of £1,000 on an acceptance of the Wire Company, discounted at the rate of 20 per cent. per annum. There is also a sum of £4,000 required to complete the needful machinery, and a further sum of £1,600, unless the buildings, &c., used jointly with the Wire Company continue available.

There is (by the works account) a stock of finished tubes of a sale value of £5,559. 4s., and of raw copper in the tanks, &c., of £2,487. 11s. 10d., together £8,056. 15s. 10d. We saw tubes in every stage of manufacture, and they appear perfect in every way. We examined into the orders received and those executed, and were gratified in finding that customers come again with frequency, and that there seems always a sufficiency of orders on the books for more than the present output. There has been produced since July 1, 1892, only 102 tons of tubes, and, by the detailed accounts rendered of cost and prices of sale, there is apparently a gross profit of about £14 per ton on the manufacture ; but, as this is at the rate of only about 1½ ton per week, the cost is naturally much more than it would be were the factory working up to its full capacity. At present the outturn looks like three tons per week, and it is stated that the present tanks at full work will produce 20 tons per week. The machinery was being worked by electric motor (during the temporary removal of the engine owing to a giving way of the foundation), so that we were unable to make any investigation on this point.

We believe that Messrs. F. Elmore and S. Elmore's services are of great value to the Company. They have held all shares allotted to them and increased their holdings, and we may say that all the Directors have fully retained their original interest in the shares of the Company.

In conclusion, we are strongly impressed with the value of the business, and advise that a strong effort should be made to provide the means for carrying it on. We deem it advisable that a new Board of Directors (preferably local men) be found to conduct the the affairs of the Company, composed of men of good business capacity (including one engineer) ; otherwise, that it would be needful, with a London Board, to have a managing engineer at Leeds, who would carry out their views and report constantly to them on the state of the work and the finance of the Company.

We think that the needs of the business would be fully met by a sum sufficient to clear off liabilities and give a clear £10,000 for the purchase of raw copper, say £17,000 in all. This being done, we think that a satisfactory and profitable business would be quickly established, with, as a result, the reinstatement of credit and clearing away of future difficulties.

We think that the launching of the Wire Company was a great mistake, and established a false financial position ; also that the prices of the licences and of the land sold to the Wire Company were unreasonable, and not justified by any evidence or examination, being practically a transfer from one Board to another Board consisting of nearly the same members.

One means of raising the required capital is the issue, as Ten per Cent. Preference Shares, of the 8,800 unissued ordinary shares, such shares to be cumulative as to dividend and preferential as to capital ; and this commends itself to us rather than other expedients which would deprive the shareholders who are willing to subscribe of their first pull at the profits.

With regard to the land, we advise, upon the authority of Mr. Gore—than whom there can be no better judge—that certain portions be put up for sale at once and disposed of, so as to relieve the Company of the charge of interest on the mortgage.

Mr. TODHUNTER added that either the shareholders had to find the money, or the Company would have to go into liquidation. He believed the business was a good one if conducted on sound principles.

The SECRETARY having read reports by Messrs. Jones and Davidson on the engineering works, by Mr. Gore on the land, and by Messrs. Ford, Rhodes, and Ford on the accounts, in verification of the statements in the Committee's report,

The CHAIRMAN said that none of the present Directors were the promoters of the Company. As to the third paragraph in the report, at the time the dividend was paid the Company had what was thought an abundance of working capital, and the dividend was passed at the general meeting of shareholders almost unanimously, and it was thought by all concerned that there would be no difficulty in earning another 50 per cent. during the twelve months which followed the payment of the dividend. As to the amount being credited or not to income, the Board was advised by its technical experts and accountants. As to the amount which was paid by the Copper Company for the Wire Company's shares upon the market being set in the balance-sheet as a good asset, he read a letter from Messrs. Price, Waterhouse, and Co., drawing attention to their certificate appearing on the Company's last accounts, which said that the accounts were correct, "subject to provision for any depreciation which may have arisen in the value of the patents (to the account of which the laboratory salaries and expenses have been carried) and in value of the investment in the shares of Elmore's Wire Manufacturing Company (Limited)."

In reference to the sum of £9,128. 2s. 11d. set down as having been paid to the Directors, the CHAIRMAN said that this sum had been divided over a period of three and a quarter years amongst eight Directors, and it included the sum of £3,930, which was the Directors' share of the profits upon the dividend actually paid to the shareholders, so that that worked out, excluding the share of the profits, to some £200 a year each. Since the date of the last report and statement of accounts, during which time the Company has been in a financial strait, the Directors have served without payment in any form. As to the land, he had at various times explained why the Company became the purchaser of its estate. He however, briefly recapitulated the circumstances, and said he was sure that, after mature consideration, and in view of the future requirements and development of business by the granting of licences for the application of the process for purposes outside of tube-making and the manufacture of sheet, it would be seen how very valuable the estate would be to them as a parent company. The Copper Company's liabilities were covered by the present stock of manufactured and raw copper and the customers' book debts. The Company had been actually making profit after payment of works charges since the date of the June report, although its output had been exceedingly small, owing to want of raw material, and he quite agreed with the Committee that when the factory was working up to its full capacity the present cost per ton would be naturally greatly reduced. That was, in fact, the point of the whole business. There was a certain fixed charge below which they could not go, and every ton of output over and above that which was necessary to cover this charge showed a large clear profit. The Directors agreed with the Committee that a sum of £17,600 additional capital would be sufficient to meet all future requirements for this business, and that this would enable them to pay for £10,000 worth of additional raw copper, which would allow them to turn out twenty tons per week. They adopted the suggestion of the Committee to issue the remaining 8,800 ordinary shares as preference shares. It was, of course, important to them to have the money immediately, and he ventured to say that there would be no difficulty in placing the small number of shares. In conclusion, he said that, notwithstanding all the difficulties and delays of the past, they had a sound and profitable undertaking in their hands, and now that the commercial working of the process had been established with certainty, future success was assured, provided that they had the necessary raw material to enable them to execute the orders of their customers. The Chairman then proposed

"That the 8,800 unissued ordinary shares of the Company be issued and be called preference shares, entitling the holders thereof to a cumulative preference dividend of 10 per cent, per annum, the said preference shares to have preference not only as to dividend, but as to capital in the final distribution of assets."

Mr. TODHUNTER seconded the resolution, which was carried unanimously.

Mr. ELMORE proposed :—

"That the Committee of shareholders, consisting of Messrs. J. Todhunter, A. Pritchard, Squire, and Owen Jones, be continued as a consultative committee, to co-operate with the present Board in making an issue of the new capital referred to, with power to accept the resignation of all or any of the present Directors, and, in conjunction with the present Directors, to nominate new Directors, and generally to advise the Board and report to a future meeting, to be called on the 28th inst."

Mr. HAYS seconded the resolution, which was carried unanimously.

A vote of thanks was then given to the Committee, and the meeting separated.

Elmore's Wire Manufacturing Company (Limited).

An extraordinary general meeting of this Company was subsequently held to receive a report of the shareholders' Committee appointed on the 16th ult., Mr. J. J. Atkinson presiding.

The Committee's report was as follows :—

"We find that an excessive price was paid for the licences, which, moreover, were accompanied by restrictions and royalty ; that the land was charged to the Company at double its cost price ; that the works have been well built, but out of all proportion to the means of the Company; and that capital has been expended both upon land, buildings, and plant, without any regard to prudent financial considerations. Consequently, three-fourths of the buildings would be practically unused, even with an output of 35 tons per week. The engines and chimney are magnificent, but far beyond any probable requirements. We believe that there is no doubt at all about the efficacy of the process, or that the difficulties

Hosted by Google

of manufacture have been overcome, and we think that there is a demand for the copper strip produced at a highly remunerative price, if the production is on a large scale. The mandrels being uniform in size, there is great simplicity in the working, once the routine arranged. This seems to us to accentuate the folly of erecting at the outset works of such enormous size, as there would have been no difficulty whatever in making additions. The accounts show liabilities £21,963. 7s. 10d., all of the most pressing kind. Expedients have been adopted, we hear, by the Messrs. Elmore to stave off proceedings, but it is evident that a settlement must be made, or the property will go out of the control of the Company. The reasons which have led up to this condition of affairs are patent from the foregoing statements, and it remains to be considered whether money can be raised, not only to meet the liabilities, but to buy sufficient raw material. We find that a sum of not less than £50,000 would be required, and that the efforts of the Directors have failed to bring an offer of more than £17,000 from those to whom they have applied for assistance, offering the security of the whole property, and these offers, in our opinion, were on ruinous terms. So it resolves itself into a question of the shareholders finding the money, or the Company being liquidated. We certainly believe that there is every prospect of success under prudent management; and if the shareholders decide on raising the money, it would, in our opinion, be in their interest to have a small Board of Directors of men of business ability and experience, who would be likely to manages the finance of the Company with prudence and economy. The inevitable alternative involves, we believe, the loss of the whole of the share capital subscribed, as under a forced sale the land, works, and machinery would not be likely to realise much more than enough to satisfy the creditors.

There is, however, another possibility by the raising of a sufficient sum to pay off the liabilities and complete the plant—say, £25,000 on debentures—and by the establishment of a Copper Supply Company, with a capital of, say, £25,000 paid up, to supply this Company with copper, together with the cost per ton for manufacture into strip, the Supply Company taking the finished strip and sheet and selling it to customers, and handing over to this Company the difference, after deducting their commission, the copper remaining the property of the Supply Company during the whole of the time. Obviously this would involve no risk to the Supply Company, and would furnish the Wire Company with raw material and working charges. We incline to advise the adoption of this latter proposal, for the following reasons :—

It necessitates only the raising of £25,000, instead of £50,000, by the shareholders, and provides good security (in the land, works, and plant) for the amount of debentures to be subscribed even in the event of failure.

The CHAIRMAN said that he had some notes to read in answer to the committee's report; but he thought he might save the time of the meeting by immediately proposing a similar resolution to that put to the parent Company.

The motion was seconded by Mr. J. W. DALE, and carried unanimously.

A vote of thanks to the Committee, and a recommendation to adopt their report, and "in view of the evident commercial success of the Elmore process" to promptly subscribe the new capital required, was carried.

Elmore's (French) Patent Copper Depositing Company (Limited).

The adjourned extraordinary meeting of this Company was held on Monday at Winchester House.

Sir JAMES MACKENZIE presided, and said that he had to begin by apologising for the absence of Major Jones, who was confined to his bed, and also for Mr. Carson, who had been unable to attend. The meeting was called in accordance with the decision arrived at at the last meeting, to consider further the prospects of the Company as opposed to the proposal of voluntary liquidation. It was considered by the minority that the only way to save the interests of the Company was by liquidation, but he did not think it was fully recognised or understood by those gentlemen who proposed liquidation what the effect of such a course would be in France. The Board knew, from what the French lawyers told them, that the interests of the shareholders and the debenture holders would be most seriously damaged, and they were quite certain that to attempt such a course at the present moment would be most disastrous. It was objected at the last meeting that the Board had nothing definite to lay before the shareholders, and therefore they asked for an adjournment, in order to see if they could not get further details. Mr. Duncan had just returned from Paris, and as he had been successful in obtaining some definite arrangement, he would call upon that gentleman to address the meeting.

Mr. DUNCAN said that he did his best to come to some arrangement with M. Sécretan by letter and telegram, but he found that that was impossible, and they were drifting further apart rather than getting nearer, and he therefore made up his mind to go at once to Paris. He had brought back with him something in the form of a definite proposal from M. Sécretan, which read as follows :—

"In presence of the present grave financial position, and with the object of avoiding an irremediable catastrophe, I beg to offer to undertake the following negotiation :—

"I propose to buy all the assets of the Company in consideration of the following :—

"1. £60,000 in First Mortgage Debentures, in payment of the present mortgages, entitled to receive £4,000 per annum interest, and sinking fund included.

"2. £20,000 in cash within three months, in order to pay off the creditors, £10,000 for the English and £10,000 for the French.

"3. £60,000 in founders' or ordinary shares, to be given to the English holders.

"I would raise a new capital of £100,000, of which £80,000 would be represented by cash and £20,000 by fully-paid shares, to be given to the French shareholders and founders. Of the £80,000 to be subscribed in cash, the right of subscription would be reserved to the present English shareholders up to one-half of the amount. If this proposal, which I only make with the object of saving the Elmore Company from a disaster caused by its financial position for which I am not responsible, is accepted, I have no doubt of being able to give effect to it. If this proposal is accepted, the present Company would be transferred into a French commandite company, under the name of E. Sécretan and Co. As soon as I receive your reply in this sense, I will have the articles of the new Company drawn up, and will submit them for your examination. It is understood that the payment of £140,000 above mentioned would entitle the new Company to all assets without exception or reserve, and that in consideration of this payment the present Company would have to make its own settlement for all liabilities without exception and reserve."

M. E. Sécretan in sending those new proposals undertook to get them accepted by his friends, subject only to the understanding that reasonable time should be given to give effect to the proposals, and also that he was furnished in the meantime with the means of keeping the factory going until the end of May, if necessary. In a subsequent letter M. Sécretan further stated that the Board of Supervision of the new Company would be composed of five members, of which two would be representatives of the English interests—one to devote himself to the business details of the concern, and the other to be, if possible, a chemical engineer, who would take up more especially the technical side of the business.

Continuing, Mr. DUNCAN said a certain time would, of course, have to transpire to allow of the examination of the documents in connection with the matter, and in the meantime the works must, of course, be carried on. Unless he, as Receiver, was prepared to carry them on in a much more enterprising way than had been the case up to that date, there must be some loss in keeping the factory going. The list of creditors in Paris had been larger than was expected on this side, and he had, therefore, increased the sum which he had allowed for the extinction of those liabilities from £8,000 to £10,000. There were also one or two other points with regard to the proposal to which he would like to allude. In the first place, the shareholders would remember that he represented that they would receive £60,000 in First Mortgage Debentures, entitled to 6 per cent. interest, which would produce £3,600. The people on the other side, however, understood that it was to be 5 per cent. interest and 1 per cent. sinking fund, but they had now agreed to give £4,000, which would amount to 5½ per cent. interest and ½ per cent. sinking fund. It was also proposed that they should receive 10 per cent. on the founders' or ordinary shares, but that went altogether against the grain of the finders of the new capital. He was glad to say, however, that they ultimately agreed to allow them 7½ per cent. The French had very substantial ideas with regard to reserve funds, and satisfactory reserves would be built up out of the profits of the Company. M. Secretan, under his original agreement with the Company, was entitled to receive 20 per cent. of the profits instead of salary, but that had now been changed to £800 a year and 10 per cent. of the profits. He was sorry to say that on this side they had not yet got rid of the creditor who was petitioning the Court, and the first necessity was to make some arrangement with regard to that matter, as it would be extremely difficult to keep the thing going in France if anything in the shape of liquidation should supervene here, and the appointment of the liquidator in France would stop all the work of the Company.

Mr. STETTELL said that at the last meeting the shareholders had two schemes laid before them—liquidation or the buying out by the French Company. He wished on that occasion to lay before them another alternative. The shareholders had received ample proof that the Elmore process could be worked successfully and with high profits, and the experts' opinions had shown the soundness of the Company's patents. He proposed that the Company should be wound up voluntarily with a view to reconstruction, and that a committee of shareholders should be appointed to draw up the prospectus of the new Company. In the scheme which he had to suggest the capital of the new Company would be the same as the old, namely, £243,782, and divided into preferred, ordinary, and deferred shares. Each holder of a £2 preferred share in the old Company would receive one £1 ordinary share in the new, and each holder of the £2 ordinary share would have one £1 deferred share in the new. The balance of capital, £121,891 in 10 per cent. preference shares of £1 each would be offered to the public, and there was, he thought, every reason to believe that the debenture holders would take up a part of that capital. He concluded by alluding in detail to the out-put of the works and the amount of dividend which might be expected upon the shares in the new Company.

Mr. STOREY, M.P., said that unless they did something that afternoon with regard to the petition against the Company, the position would be bankruptcy. He would like to know if the Chairman or Directors had any proposals to make.

The CHAIRMAN said that the Directors did not recommend liquidation, they suggested the alternative course as set forth by Mr. Duncan.

Mr. STOREY, M.P., said that the Court would take no more notice of an offer from M. Sécretan than they would of an offer from Mars. He proposed that the Directors and secretary should pay off the petitioner out of their salaries, as he thought that they were the only ones who had received anything from the Company. If they paid the one amount off every other creditor would take the same course. The Directors had been chosen by the Company, and were paid by the Company, and he considered that they ought to lay some proposal before the shareholders.

Mr. MADDISON said that he thought if the meeting were postponed till five o'clock he might be able to make some arrangement.

After some discussion several shareholders subscribed various amounts in order to delay the petition, and the meeting was adjourned.

Hosted by Google

At 5 p.m. the proceedings were resumed, and Mr. MADDISON stated that he had been able to get the petition postponed for a month. There was another amount of £250 behind the first petition, and £64 behind that, but he was pleased to say he had been able to come to a satisfactory arrangement.

After some further discussion the following resolution was proposed by Mr. MADDISON, seconded by Mr. STOREY, M.P., and carried unanimously :—

"That this meeting taking favourable note of the proposal of M. Sécretan as reported by the Receiver, it is resolved that the meeting stands adjourned until May 8th at two o'clock, at Winchester House, and that a committee be appointed to confer with Mr. Baker as to the best method of carrying out arrangements with M. Sécretan, or otherwise doing what is best for the interests of the Company."

Messrs. S. Storey, M.P., J. Wood, J. Heal, F. Stettell and Colonel Shepherd were elected a committee.

Mr. STOREY, M.P., moved that a special extraordinary meeting should be summoned to be held after the adjourned meeting, which was carried.

Eastern Extension, Australasia, and China Telegraph Company (Limited).

The following is the report of the Directors for the half-year ended December 31, 1892, to be submitted to the thirty-ninth ordinary general meeting, to be held at Winchester House, E.C., on Wednesday, the 19th inst., at 2 p.m. :—

The gross receipts, including Government subsidies for the half-year ended December 31, 1892, have amounted to £247,766. 19s. 1d., against £243,658. 8s. 10d. for the corresponding period of 1891.

The working and other expenses, including £38,103. 1s. 1d. for cost of repairs to cables and expenses of ships, absorb £91,768. 18s., against £74,314. 9s. 5d. for the corresponding period of 1891, leaving a balance of £155,998. 1s. 1d. From this is deducted £6,030. 8s. 3d. for income-tax, and £31,895 for interest on debentures, debenture stock, and contribution to sinking fund, leaving as the net profit for the half-year £118,072. 12s. 10d., which, with £70,271. 1s. 9d. brought forward from the previous half-year, shows an available balance of £188,343. 14s, 7d.

One quarterly interim dividend of 1½ per cent. has been paid for the half-year, and it is now proposed to distribute another of like amount on the 20th inst., making, with the interim dividends paid for the first half-year, a total dividend of 5 per cent. It is also proposed to pay a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the year 1892. The balance of £75,843. 14s. 7d. has been carried to the general reserve fund, which, after being credited with interest received on investments, now stands at £509,732. 19s.

The alterations of tariff with the Australasian colonies, to which reference was made in the last report, came into force on January 1st last, and the result so far is encouraging.

Since the close of the half-year, the tariffs at the stations affected by the serious depreciation in the silver currency have also been adjusted, so as to avert, as far as possible, the loss on exchange from which the Company has so long suffered, and which during the past six months amounted to the large sum of £11,692.

In accordance with the provisions of the trust deed dated May 15, 1879, 353 of the Company's Five per Cent. Australian Government Subsidy Debentures, amounting to £35,300, were drawn by lot on the 6th instant for payment at par on July 1st next. The numbers of the drawn debentures are given on page 12 of the report.

The Company's maintenance ships have as usual been employed on various repairs during the half-year under review, but, owing to most of the cables being duplicated, the traffic has not been materially affected.

In accordance with the Articles of Association, Sir John Pender, G.C.M.G., M.P., and Sir James Anderson retire by rotation, and, being eligible, offer themselves for re-election. The retiring auditors, Mr. Henry Dever and Messrs. Welton, Jones and Co., also offer themselves for re-election.

WOODHOUSE AND RAWSON UNITED (LIMITED).

As intimated in our issue of the 7th instant, a special meeting of the debenture stockholders, debenture holders, and trade creditors of this Company was held on Monday last, at the Cannon-street Hotel, under the presidency of Sir Rawson W. Rawson.

The CHAIRMAN said : Gentlemen, my co-trustee, Mr. Samuel Pope, Q.C., and myself have felt it our duty as trustees for the debenture stockholders of this Company, to call you together, and at the same time to invite all those who have an interest in Woodhouse and Rawson United to come to the meeting to-day, to consider their position, and to take such action as they shall agree is for the greatest interest of the Company, and which will give them the largest amount of return possible from the assets of the Company, and not allow those assets to be dissipated either by interested or hostile parties. The circumstances are set forth in a circular which has been addressed to you by Mr. Pope and myself. A few weeks ago a receiver was appointed upon the application of a gentleman largely interested in the Company, and who certainly bears the Company no ill will, and in taking that action he has no desire whatever to injure anybody else concerned in the Company. Since then the general meeting has been held—which I was unhappily unable to attend—and at that meeting it was decided that we should go into voluntary liquidation, and at that meeting a liquidator was appointed. The Directors were of the opinion that that arrangement was the best in the interest of all parties concerned. You will bear in mind that this meeting is called by the trustees, and not by the Directors. It happened—and I think Mr. Pope regrets it equally with myself—that two or three years ago he and I, although Directors of the Board, were also appointed trustees. It would have been better if the offices had been separated. But I can tell you this, that in our position of trustees we have not neglected the interests of the debenture holders. Now, as regards the question of liquidation, we believed that voluntary liquidation would be the best course to pursue in the interests of all concerned. Well, since then, actions have been brought against the Company, as stated in our circular. One of these actions has been brought by a debenture holder for an amount of £250, and the other from a creditor of £185—small matters—and each individual has thought that he was consulting his own interest best in forcing the Company into compulsory liquidation. Those motions will come on for hearing to-morrow, and the object of the trustees in calling you together to-day is to get an opinion from the debenture holders, the debenture stockholders, and the creditors in the Company, as to whether they considered it in their interest to liquidate the Company voluntarily, as already arranged, or to be forced into compulsory liquidation. Voluntary liquidation would, of course, be under the supervision of the Court ; there would be no objection to that. Therefore, the question that we desire any expression of opinion upon is whether we shall take action to resist these motions for voluntary winding up. You are aware that in the case of compulsory liquidation, the assets of the Company are thrown upon the market whether there be any demand for them or not, the object of the official liquidation being to wind up the Company as speedily as possible, without reference to what might be obtained by a little time and a little patience. The assets of this Company are specially liable to depreciation by a compulsory liquidation, because they are not articles of great demand, and the present time certainly is not the time to put upon the market electrical apparatus, electrical stock, and electrical plant, or the goodwill of the business—the trading business of this Company. There is every reason to believe that in a short time some improvement will arise, but it is certain that the present time is about the worst that could be chosen to force a compulsory liquidation. We believe that voluntary liquidation is advisable under some such arrangement as was suggested at the general meeting, for reconstruction or otherwise, so that the assets of the Company might be secured in the best possible way in the interest of all those who are entitled to share in them. It is for that purpose that Mr. Pope and I have invited you to meet us here to-day to consult upon that point, and, if you are agreed, to give expression to your opinion that it is not desirable to submit to compulsory liquidation, but that it is desirable to proceed to voluntarily liquidation. I regret that for the past month or two it has not been possible for me to attend to these matters as I could have wished, but Mr. Pope and the Managing Director (Mr. Rawson) will give you any further information that you may require, and then you will act upon your own judgment, and I hope that it will result in the meeting determining that voluntary liquidation is the course to be adopted.

Mr. SAMUEL POPE, Q.C., said he was rather anxious that they should carefully understand what they were met to discuss that morning. Unfortunately, as they knew, Sir Rawson W. Rawson and himself were Directors of the Company. Whatever blame, in the judgment of some, might be attachable to the management of the Company, they, as Directors, must bear their share of ; but they were also trustees for debenture holders, and that had been the reason why they had called them together that day, in order that they might make up their mind as to which course was the best to pursue in the interest of all the creditors of the Company. Putting aside for a moment the interest of the Directors and the shareholders, what was best to be done for the debenture holders, the debenture stockholders, and the creditors of the Company ? It would be recollected, he dared say, what took place at the meeting in December. It was at that meeting that the unfortunate balance-sheet which had been the cause of all these subsequent events was presented to the shareholders. He desired as much as possible to keep the business of the day to the matter in hand, and would not, therefore, with the permission of the meeting, refer to the position of the shareholders and their interests, although he held a very strong view as to what would be the best thing for the shareholders to do. He was quite sure the interest of the debenture holders, for which he was more immediately responsible, was to secure the best possible realisation of the assets of the Company, which were held as their security. It seemed to him that they could not adopt a more ruinous course than to force these assets upon the market at a "break-up" price. He regretted the course that had been taken by those who had brought actions against the Company for compulsory liquidation. It was, therefore, for that meeting to decide whether they would allow the proceedings to be conducted voluntarily, or whether they would put the Directors to the disagreeable alternative of having to submit themselves to the examination of the official receiver. As to the possibilities of a satisfactory realisation of the assets if care and patience were exercised, the Committee of shareholders had—although he did not agree with the low valuation they put upon the assets—said that even at the low value at which they had taken them they would, if intelligently realised, be, they believed, sufficient to meet the liabilities of the Company. The question of a reconstruction could not, of course, be gone into in any detail at that meeting. Having explained a mistake he made at the last meeting in attributing to the general manager, Mr. Stutchbury, the statement that the profits from the industrial part of the undertaking would be £30,000 a year, and explained that the sum should have been £10,000 to £14,000.

A SHAREHOLDER asked what would be the position that the unsecured creditors would occupy in a reconstruction scheme.

Mr. POPE : The scheme, as I understand it, is to leave them exactly the security that they have at present.

A VOICE : They have none.

Mr. POPE said that in that Company there were three classes of liabilities that took preference of the shareholders, viz., the debenture stock-

Hosted by Google

holders, the stockholders, and the unsecured creditors. He concluded by moving the following resolution :—

"That this meeting of debenture-holders, debenture stockholders, and creditors of the Company approve of liquidation under supervision of the Court with a view to reconstruction, and do not approve of compulsory winding up."

Mr. DODSON proposed as an improvement on the Chairman's resolution the following, which was accepted by the trustees, viz. : —

"Resolved : That, in the opinion of this meeting, it is undesirable for the Company to go into compulsory liquidation, and that Mr. Alexander Young, of the firm of Turquand, Youngs and Co., be retained as voluntary liquidator under the supervision of the Court, with a view to carrying out a scheme of reconstruction."

Mr. ACKWORTH seconded the resolution.

Mr. STUTCHBURY (General Manager) then addressed the meeting. He said that he could endorse every word that he said at the meeting in December. As he said then, the falling off that they suffered from they had suffered from in common with other concerns. Their industrial business was good, and since the appointment of Mr. Leslie as Receiver their position had been furthered strengthened, and they were receiving constant inquiries from every part of the world, and satisfactory orders were coming in ; their various agents were doing good business, and only that morning some good orders came in from South Africa, and these orders gave a very satisfactory profit.

Mr. LESLIE (Receiver) endorsed the remarks of the general manager. When he took possession of the business on March 10th he found the management in an almost chaotic state. He had cut down the weekly wages from £138 odd to about £95, equal to a saving of £2,200 a year ; he had closed one house, saving thereby some £600 in rent ; he was endeavouring to have all contracts carried out thoroughly ; he had visited the various works, and was leaving that evening for a further inspection ; he believed that with business-like management they had the nucleus of a very good business, and he believed they would succeed ; but if a compulsory liquidation was forced upon them, he did not believe they would pay 10s. in the £ to Debenture Stock holders. Therefore it was evident that compulsory liquidation would be a very great mistake.

Mr. RAPHEAL said they had received no particulars as to any reconstruction, and no details of what it was proposed should be done.

Mr. POPE said that it would be the duty of the Receiver to bring forward any scheme of reconstruction that might be deemed advisable. They could not, of course, say what that gentleman might elect to do, but the rough outline of the proposed reconstruction scheme was contained in the Trustees' circular [published in our last issue].

After some noisy discussion, the resolution which had been moved by Mr. DODSON and seconded by Mr. ACKWORTH was put to the meeting and carried with only one dissentient.

Mr. MADDISON then expressed the opinion that it would be desirable to appoint a committee to confer with the receiver on the question of the realisation of the assets.

A discussion ensued upon this, and eventually it was decided that Messrs. Dodson (of Reuter's Telegram Company), Benage, White, and a representative of Henley's Telegraph Works Company should be appointed a committee to confer with Mr. Leslie (the Receiver) upon the question of the realisation of the assets of the Company.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

FOREIGN ELECTRIC DATE AND TIME STAMP COMPANY (LIMITED).—At meetings held on March 3rd and 20th resolutions were passed and confirmed—that it is desirable to reconstruct the Company, and accordingly that the Company be wound up ; that Richard Warner, 32, Walbrook, auditor, be liquidator ; and that the liquidator consent to the registration of a new company, to be named the Foreign Electric Date and Time Stamp Company (Limited).

NOTTINGHAM ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—At meetings held on March 11th and 29th it was resolved that the Company be wound up ; and that Walter Griffith, Low-pavement, Nottingham, be liquidator.

PLANET ELECTRICAL ENGINEERING COMPANY (LIMITED).—The annual return of this Company, made up to July 26, 1892, has been filed. The nominal capital at the time of making up the return was £20,000 in £5 shares (since increased to £30,000 in £5 shares), and 3,382 of these shares have been taken up. Of these 800 have been issued as fully paid, while upon the remaining 2,582 shares the full amounts have been called, and all calls (£12,910) paid. The principal shareholder is Mr. R. W. Wallace, who holds 1,050 shares.

PYKE, HARRIS, AND COMPANY (LIMITED).—Particulars have been filed of the sale to and purchase by this Company of the business of electrical engineers carried on by Lazarus S. M. Pyke and Edward Harris, of 34, New Tothill-street, Westminster, S.W. The vendors agree to sell their businesss, together with their interest in patents—Nos. 11,503 (1888), 3,900 (1890), 4,004 (1890), 22,785 (1891), 21,541 (1891), 17,818 (1891) and Provisional Protection 19,222 (1892), for £2,000 in cash, and the allotment of 3,600 fully paid up "B" shares of £5 each.

SCARBOROUGH ELECTRIC SUPPLY COMPANY (LIMITED).—The statutory return made up to March 24th has been filed. Of a nominal capital of £50,000, in £10 shares, 1,980 have been taken up. Upon these shares a call of £4 per share has been made, resulting in the payment of £7,912, leaving £8 arrears.

UNITED ELECTRIC TRAMWAYS (LIMITED).—The statutory return o this Company, made up to March 6th, has been filed. 157 shares have been taken up out of a total of £30,000, in £5 shares, and the full amount has been called. The calls paid amount to £35, while these in arrears amount to £750.

WALSALL ELECTRICAL COMPANY (LIMITED).—An agreement dated March 8th last between Frederick Brown, of Walsall, electrical engineer, and the Company states that, by an agreement of December 9th last between the same parties, it was agreed that the vendor, Mr. Brown, should sell to the Company the goodwill of the business carried on by him at Walsall and Birmingham under the style of "The Walsall Electrical Company," together with the benefit of certain inventions and letters patent, for the sum of £1,000, and the plant, &c., for £1,450, and the same agreement appointed the vendor Managing Director of the Company with a salary of £350 per annum, and 25 per cent. of the net profits, and and also stated that the purchase consideration should be paid £450 in cash and £2,000 in fully paid shares. The present agreement determines that 200 shares, each considered as fully paid, shall be allotted to the vendor, and that the cash payments due shall be immediately satisfied by the Company.

W. T. HENLEY'S TELEGRAPH WORKS COMPANY (LIMITED).—The annual return of this Company, made up to March 31st has been filed. The nominal capital is £100,000, divided into 7,000 ordinary and 3,000 preference shares of £10 each. 6,837 ordinary and all the preference shares have been taken up, the full amount called, and all calls (£98,370) paid.

MISCELLANEOUS.—BEESTON FOUNDRY COMPANY (LIMITED), iron and brass founders, electrical and mechanical engineeers, &c. ; capital, £15,000 in £10 shares.——FOSTER AND PEARSON (LIMITED), heating, electrical, and general engineers, iron and brass founders, &c. ; capital, £15,000 in £10 shares.——PICKERING, SWAIN, AND CO. (LIMITED), steam, pneumatic, hydraulic, electrical, mechanical, and general engineers and metal workers ; capital, £10,000 in £1 shares.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—Notice is given that the seventh drawing for payment of the Five per Cent. Debentures (1884 issue) will take place on Monday next, at noon, at the offices of the Company.

BRIGHTON EIFFEL TOWER AND WINTER GARDENS (LIMITED).—A supervision order in the winding up of this Company has been granted, the voluntary liquidator being instructed to inquire into the matters alleged in the petition, and make a report to the Court.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended April 9th were £842, as against £742 for the corresponding period of last year, being an increase of £100. The total receipts for half-year amount to £12,856 against £11,761 in the corresponding period of 1892, being an increase of £1,095.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—Our advertisement columns contain a list of 353 Five per Cent. Australian Government Subsidy Debentures of £100 each, drawn by lot on April 6th last at the offices of the Company. These debentures will be paid off at par on July 1st next, at Messrs. Barclay, Bevan and Co.'s bank, 54, Lombard-street, E.C., interest ceasing after that date.

INDO-EUROPEAN TELEGRAPH COMPANY (LIMITED).—The Directors of this Company, after adding £10,000 to the reserve fund, have determined, subject to audit, to recommend the payment of a dividend for the six months ended December 31, 1892, of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent. per year, and a bonus of 20s. per share, both free of income tax, making in all 10 per cent. for the year. The dividend and bonus will be payable on and after May 1st next.

HOBART TRAMWAYS COMPANY (LIMITED).—A meeting is to be held at College Hill-chambers, E.C., on Monday, the 24th inst., at 2.30 p.m., for the purpose of confirming the resolution passed at the meeting held on the 6th inst., altering the name of the Company to The Hobart Electric Tramway Company (Limited).

MIX AND GENEST (BERLIN).—At the fourth annual meeting of this Company, recently held, a dividend was declared for 1892 of 6 per cent.

NATIONAL TELEPHONE COMPANY (LIMITED).—The Right Hon. Lord Balfour of Burleigh has joined the Board of this Company, and will assume the position of Vice-President of the Company.

STOCK EXCHANGE NOTICES.—The Committee of the Stock Exchange have ordered the further issue of 4,120 ordinary shares, Nos. 454,748 to 458,867 of the National Telephone Company (Limited), to be quoted in the Official List.

SUBMARINE CABLES TRUST.—Notice is given that a payment of £1. 10s. will be made on account of the coupon due on April 15th on and after that date, by Messrs. Glyn, Mills, and Co., of 67, Lombard-street,

Hosted by Google

London, E.C., between the hours of 10 a.m. and 2 p.m. The coupons should be left with the bankers for examination four clear days before payment. They will be stamped with the words "£1. 10s. paid," and returned to the holders.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended April 7, 1893, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,692.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 779.—Vol. XXX. FRIDAY, APRIL 21, 1893. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

So much attention has been given, of late, to central station work, that the design and management of comparatively small isolated plants has been left rather to rule of thumb. One great advantage of the best class of rule-of-thumb work is that breakdowns and hitches are eliminated. By rule of thumb we understand a common sense following of tradition, founded on experience. Whatever has been found to work well is retained, and whatever has led to failure is rejected. Progress, however, under this rule is very slow, and some care should be given to examine what is really meant by working "well." Lamps marked for 100 volts run well at 100 volts, but Mr. Kapp in his lecture at the Society of Arts on Wednesday showed how £21 per annum might be saved by running 100 lamps, used 100 hours a year, at 3 watts instead of $4\frac{1}{2}$ watts per candle, and how when gas engines are worked with expensive gas a similar course should be adopted. The introduction of a new or somewhat modified definition of the term "load factor" in the course of Mr. Kapp's lecture is rather unfortunate. It is quite possible that Mr. Crompton's original definition is not easily applicable to isolated plants, but inventors of new definitions should supply new names. These modifications will result in somebody speaking of the ratio of the number of lamps he has got in his house to the number he would like to have, as his load-factor. Storage batteries are a serious burden on the cost of lighting. If it were not for the heavy first cost, maintenance, and skilled labour which batteries entail, an isolated plant could beat a supply company for all sizes down to one or two hundred lamps. An interesting table of costs of electric lighting in various private houses, clubs and Government buildings was given by Mr. Kapp.

An unusually interesting collection of exhibits was shown at the Institution of Civil Engineers on Tuesday, at the monthly reception by the President and Council. *Apropos* of the Paper under discussion, the engine on which Mr. Willans' non-condensing trials has been made was shown cut in half, displaying the pistons and central valves, thus allowing the course of the steam to be easily traced. Parts of a 60 I.H.P. Willans engine, all, in fact, except the base, were also shown. This engine had been driving the dynamo for electric lighting and power at Thames Ditton since July, 1889, and had run for a period equivalent to about five years of ordinary work. The wear had been very small indeed. This engine was stopped at 1 p.m. on Tuesday last, was removed during the dinner hour, replaced by another erected from parts taken from store; the latter was started at 2 p.m. while the former was exhibited on the same evening at Great George-street. Close to this engine was the trunk of a fan-engine from the Woodthorpe Colliery. This engine, as was mentioned in our obituary notice of Mr. Willans, had run for as long as nine months without being stopped, and was locked up by itself at night. This trunk showed no perceptible wear and has a fine dark polish. Americans and others fond of big things may be interested to hear that this trunk had made 1,600,000,000 strokes. Besides the Willans exhibits were a number of standard parts of G.E.R. locomotives, the valve gear of a London, Tilbury and Southend locomotive, and numerous models. Among these was a working section of an ingenious engine designed by Mr. Grafton, and which is being made by Messrs. Easton and Anderson; it has pistons which approach and recede from each other in the same cylinder.

Among the regulations and conditions which the Board of Trade are empowered to make under the Electric Lighting Acts is one which prescribes that in high-pressure supply, where a transformer is provided on the consumers' premises, some means or apparatus approved by the Board of Trade shall be provided which shall render it impossible that the low-pressure service lines and consumers' wires shall be at any time charged to a dangerous difference of potential from the earth, owing to accidental contact with, or leakage from, the high-pressure conductors, either within or without the transformer. The best-known types of apparatus which have been proposed for this purpose are the Cardew and the Drake and Gorham devices, differing, indeed, but little from each other, and depending on the static attraction of an aluminium leaf, the Ferranti device of a fuse and suspended contact plug and that of Sharp and Kent, an earthed metallic separation. This consisted originally of a sheet of metal between the primary and secondary windings of a transformer; but it has more recently been modified, and the sheet is replaced by a winding of wire, open circuited, of course, and put to earth. This, and certain other regulations, have offered a fine field for an ambitious inventor, who, it is conceivable, might have covered the whole ground in each case by one or more wide-reaching patents. With the exception of a patent for sealing meters, no attempt appears to have been made to take advantage of these regulations in any such manner. It is not often that the inventor is offered opportunities of this kind; he

Hosted by Google

generally has to seek for, or to artificially create, the long-felt want. The Sharp and Kent device for meeting this particular regulation has met with the approval of the Board of Trade, but not, we understand, to the exclusion of others. There is a good deal to be said for the use of separate apparatus which may be attached to existing circuits, for it is too much to expect that consumers on high-pressure circuits, who are already mulcted by rentals for transformers, should be asked to take them out and have them re-wound according to this ingenious and approved method.

THE Metropolitan Electric Supply Company, the annual general meeting of which takes place to day, is the biggest of our electricity supply concerns, and for that very reason its operations do not easily admit of comparison. Its five generating stations supply current to 134,463 lamps spread over an area of more than 4½ square miles, the district being of a peculiarly varied character. The dividend is not exactly handsome, but the accounts show that, like the rest of the London companies, the Metropolitan has increased its lamp revenue and decreased the absolute cost of production of the Board of Trade Unit. In 1891 the sale of current brought in £37,767, disregarding the odd shillings and pence; last year the figure was £50,852, an increase of some 34 per cent. On the other hand the total generating expenses have only grown by about 3 per cent., all items save coal and repairs actually showing a decided diminution. In a continuance of this process lies the financial success of the undertaking.

THERE is an almost irresistible tendency to take a semi-jocular view of the municipal electric light deputations which have of late been so frequent. If, however, they all bear as good fruit as has been the case with the Special Electric Lighting Committee of the Vestry of St. Mary, Islington, whose voluminous report lies before us, it is time we took these tours seriously. Disregarding a report advising the adoption of a low-pressure system for Islington, the Committee proceeded to pay the usual round of visits to central stations. The net outcome is a well-argued recommendation to the Vestry—a recommendation which was adopted on Tuesday—to undertake the electric lighting of Islington itself, to lay down a 20,000-light alternate-current central station, and to obtain borrowing powers to the extent of £60,000. We feel that we are not sufficiently well acquainted with the district in question to endorse the Committee's estimate of its suitability for electric lighting, but taking that estimate as correct, the anticipation of the Committee that the venture will be "an assured commercial success," will in all probability be fulfilled. The noteworthy feature of this particular report is the unusually accurate appreciation of the relative merits of the various systems which this non-technical Committee arrived at, the "diverse and contradictory" opinions of advocates notwithstanding.

UPON glancing through the pages of a well-illustrated pamphlet sent us by the Durham College of Science and addressed to its "Governors and other friends," we are inclined to think the finance of this institution as venturesome as its intentions are good. The existing buildings at Newcastle were, it appears, erected and equipped at a cost of about £24,000; "of this sum £17,000 has been borrowed, and the interest is a standing charge against the revenue of the College;" the shell of the buildings now in course of erection is estimated to cost about £20,000, "towards which about £10,000 is in hand." Since the cost of equipping the new Engineering Laboratory will need £12,000, about £22,000 is "*immediately required*, if the new buildings are to be opened in October efficiently equipped without increasing the liability already existing upon the College." The suggestion is made that gifts in kind will be as acceptable as money, and that if no single firm or individual will present the new laboratory with the set of quadruple-expansion marine engines designed by Prof. WEIGHTON, a number of engineering firms might each contribute a portion—crank-shaft, cylinders, valve-gear, &c., &c., Prof. WEIGHTON undertaking the responsibility—which would certainly be no light one—of converting these assorted contributions into an engine. In addition to all this, we are told that £90,000 should be forthcoming "at no distant date," to complete and equip a new wing and to clear off existing liabilities. In conclusion, it is stated that during the last three or four years "the College income has nearly balanced the expenditure" though this has only been brought about by the teaching staff "placing the financial interests of the institution in front of their own," that is to say, by their surrendering fees and providing laboratory apparatus.

WHETHER or no the Durham College of Science is all that it should be from the point of view of financial management, the product that it turns out, and its adaptation to its environment we know not; but we do not hesitate to say that no institution of the kind should be permitted to continue to drag out an existence by such self-sacrificing devices on the part of its professorial staff. We are constantly being told that every loafer—we beg pardon, we mean labourer—is worthy of his hire, and we know of no reason why the term "labourer" should not include, "professor," even if he "plays" for six months in the year. Education has always been an object of endowment, and in an engineering centre like Newcastle an institution giving instruction in the science of the engineering profession should surely not be stinted in funds, if it has a right to exist at all.

Nelson.—The Local Government Board have sanctioned the borrowing by the Corporation of £6,000 more to complete the electric lighting scheme.

Burton-on-Trent.—On Thursday last week a Local Government Board inquiry was held to consider the borrowing of £11,500 for electric lighting.

Cable Interruptions and Repair—

Cables.	Date of Interruption.	Date of Repair.
Gibraltar-Tangier	February 18th	April 1st
Para-Maranham	March 20th	—
St. Thomé-Loanda	April 11th	—
Accra-Grand Bassam	April 11th	—
Paramaribo-Cayenne	April 15th	—

Marine Electric Lighting.—Our contemporary *Electric Plant* has published a digest of current information on the subject of electric lighting on board ship, in the shape of a profusely

Hosted by Google

illustrated special number. The compilation ought to prove of service to firms desirous of pushing their ship-lighting departments.

Municipal Electrical Engineers.—Frankfort-on-the-Main is to have a municipal electrician, with a salary of £500 a year and a share of the profits of the electric-lighting station. These figures are an improvement upon the market rate obtaining at home.

The Brighton-Rottingdean Electric Railway.—The National Telephone Company, who were the only opponents to this Bill, have given notice of the withdrawal of their opposition, the promoters having agreed to insert a clause for the protection of their wires. The withdrawal of this petition leaves this projected railway entirely unopposed.

Electrical Communication with Lighthouses.—The Royal Commission inquiring into the best possible means of electric communication between lightships, lighthouses, and the shore at various points on the British coast, will commence a second series of visits to the most dangerous parts of the coast on July 10th. The exact route has not yet been settled, but it is understood to embrace the north and west coasts of Scotland and England.

Mr. Falkenstein's Paper on Electricity in Tanning.—A supplementary note at the end of Mr. Falkenstein's Paper, which we printed last week, referred to a diagram A_2, showing the relation of rate of flow with current. The vertical scale of this diagram, which was given on page 688, was lettered by a mistake of our engraver "differences of levels in millimetres" instead of "current in amperes," the horizontal lines denoting 0·005, 0·010 ampere, &c.

Tramways v. Telephones.—A Paper was read on this subject by Mr. S. Sellon at a meeting of the Tramways Institute at Liverpool on the 13th inst. The protection clauses of the National Telephone Company were discussed, and reference was made to the Leeds case and the Sandgate and Hythe case. The objects of the Electric Traction Association were explained, and an appeal was made for a strong combination to defend electric traction against the attacks of the Telephone Company.

Inter-Colonial Electric Lighting Conference.—A committee of experts appointed to draft a code of rules and regulations for electric light and power wires met at the General Post Office, Sydney, last month. The representatives were convened by Mr. Charles Todd, Postmaster-General of South Australia. The representatives of the various colonies were as follow:—Messrs. C. Todd, Postmaster-General and Superintendent of Telegraphs for South Australia; P. B. Walker, Secretary of Telegraphs for New South Wales (also representing Queensland); George Smibert, Electrician in the Victorian Telegraph Department; R. Henry, Superintendent of Telegraphs for Tasmania; also the following representatives of the electric lighting companies:—Messrs. O. Haes, of the Brush Electric Light Company; A. J. Arnott, City Electrician, Melbourne; and J. O. Callender, of Sydney.

Edinburgh.—The following memorial against the Town Council working the Electric Light Order themselves is being largely signed by the Princes street and other shopkeepers. It will be presented to the next meeting of the Town Council:—

> We, the undersigned citizens of Edinburgh, observing that the Lord Provost's Committee have decided to recommend the Town Council to take into their own hands the lighting of the city by electricity, humbly desire to express our conviction that such a course would be against the best interests of the city, looking to the fact that there is a thoroughly substantial local company willing to take the initiative risk. Some of the advantages which the citizens as a whole would derive, should the Town Council delegate the electric lighting to a local company, would be as follows:—(1) None of the citizens who are not consumers would be taxed for the introduction of this new illuminant; (2) a company is in a better position to carry through the undertaking more satisfactorily than the Town Council, seeing that the members of the latter are already overtasked; (3) a company would be more popular with all classes of the community, and consequently would be able to secure a very much larger number of consumers.

A special meeting of the Town Council has been called for to-day to decide as to what steps shall be taken in regard to electric lighting.

The Gilgit Telegraph Line.—There seems, says the *Indian Engineer*, every prospect of a good working line of telegraph being established this summer between Srinagar and Gilgit. Before winter set in, an experimental wire was laid from a point 12,000ft. high on the passes into Srinagar, a distance of 42 miles. Tests have shown that this has stood the trying ordeal of heavy snowfall and severe frost, the insulation being quite satisfactory. When the hot weather has set in, work on the line will be proceeded with as quickly as possible, and by the end of next autumn the line should be completed through. Then Gilgit will no longer be cut off from telegraphic communication with India for months together, as is now the case. Mr. Olphert will have charge of the construction, a special sub-division being formed to facilitate operations. A second wire, it may be added, is being laid from Srinagar to Mari by the Indian Telegraph Department, which took over the Durbar line a few months ago.

Transmission of Indian Telegrams.—Referring to the Indo-European Department, and the change by which it will again have a Director-in-Chief of its own, it may be noted, says the *Indian Engineer*, that the direct administration of the line has been most successful. The arrangement, in fact, might well have continued had it not been that the extra duties thrown upon the Indian Telegraph Department were excessive, particularly as the growing telegraphic wants of this country had to be attended to in the first instance. The Indo-European cables and land lines were always well found, and the superintendence was extremely good under the original system of management. What the Indian Telegraph Department has done has been to quicken the rate of transmission, and thus bring Europe and India more in touch. The number of words signalled in 1888-89 was 3,870,000, and the mean of the time taken in signalling each message was 14 minutes; in 1891-92 the words had risen to 4,587,000, and the mean rate had dropped to seven minutes only. Thus, though the work had increased by 730,000 words, each message was disposed of in half the time formerly taken. A great advance this, and one which reflects the highest credit upon the Indian Telegraph Department.

Bradford.—A special meeting of the Gas and Electricity Supply Committee was held on Friday last to consider what steps should be taken during the summer months to extend the Electrical Works so as to cope with an increased demand in the winter. Alderman Priestman presided. He said the main point to which the Committee should direct their attention was whether they should extend their plant on the two-wire system, or start afresh and employ the three-wire system. Mr. Sydney W. Baynes, Electrical Engineer to the Corporation, presented to the Committee an exhaustive report on the subject. He stated that the pressure throughout the area lighted was very unequally distributed. The demand for light and motive power was now growing so rapidly that the distributing mains were inadequate. To double the present two-wire mains would cost £9,630. 10s. Mr. Baynes estimated the cost of the three-wire system at £5,970. 3s. 4d., a capital saving of £3,660. 6s. 8d. There would also be a saving in working expenses of £424. 10s. To meet the demand for next winter he estimated that 200 to 300 additional horse-power would be required. The Committee spent upwards of two hours in considering the question, and finally decided that a sub-committee should be appointed to go into the whole question, and bring up a further report.

The London County Council Technical Education Board.—The following are the names of the members of this Board:—Earl Compton, Messrs. Spicer, Hogg, Bayley, Webb, Collins, Beachcroft, Ward, Forman, Wood, Stuart, Crooks, Orsman, H. R. Taylor, Leon, H. P. Harris, Fardell, Steadman, Chatterton, and Roberts, representing the London County Council. From the various bodies having representation on the Board the following 13 nominations had been received:—School Board for London (three), Mr. J. R. Diggle, General F. J. Moberly, and the Hon. E. Lyulph Stanley; London Trades Council (three), Miss Frances Hicks, Mr. G. Courtenay, and Mr. G. Shipton; City and Guilds of London Institute (three), Mr. H. C. Saunders, Q.C., Sir O. Roberts, and Dr. W. J. Russell, F.R.S.;

Hosted by Google

trustees of the London Parochial Charities (two), Sir Philip Magnus and Mr. C. J. Drummond; Head Masters' Association (one), the Rev. G. E. Mackie; National Union of Teachers (one), Mr. T. A. Organ. All these were duly elected. To fill the places of the remaining two members (one, at least, of whom, by a resolution of the Council, should be a woman), Mr. H. Llewellyn Smith and Mrs. Sophia Bryant, M.A., D.Sc., were elected. By a further resolution the Board thus constituted will continue for one year with all the powers of the Council under the Technical Education Acts, 1889 and 1891, other than that of raising a rate.

The Electrical Trade Section.—The following paragraph from the Eleventh Annual Report of the Council of the London Chamber of Commerce, referring to the past year's work of the Electrical Trade Section, may be of interest :—

During the year this Section has held three meetings, in addition to a considerable number of meetings of special committees appointed to deal with various subjects. One of the most important matters dealt with was the County Council Bye-Laws for the Regulation of Overhead Wires under the Act of 1891. A special committee was appointed to take what action might seem necessary in regard to the bye-laws, and, as a result, a petition was prepared and sent to the President of the Board of Trade, pointing out the impracticable nature of many of the proposed bye-laws. This was followed up by a deputation to Sir Courtenay Boyle at the Board of Trade, and it is satisfactory to state that the bye-laws were ultimately settled to the general satisfaction of the industry. An attempt was made to organise a representative electrical exhibit for the Chicago Exhibition, but as the suggestion did not meet with sufficient support, the matter was allowed to drop. A special committee was also appointed to consider the possibility of reconciling the rival claims of the traction and telephone companies as to the "use of earth." A number of gentlemen were appointed arbitrators to act in the settlement of any disputes arising in the trade under the rules and regulations of the London Chamber of Arbitration. The Section has agreed to follow the precedent of other Sections by abolishing its Standing Committee, and convening the whole of the membership to all future meetings. Other questions discussed included the relation of the Association for the protection of telephone subscribers to the Chamber, electrical communication on the coasts, merchandise marks, standardising of electrical machinery, and uniformity of prices."

The Future of Arc Lamps.—There is no mechanism used in electric lighting so little studied as the arc lamp, says *Industries*. The average electrical engineer knows less about the underlying principles and the actual working of arc lamps than of any other part of his business. No good work has been written on the subject, the nearest being an able Paper by Prof. S. P. Thompson. The full theory of the arc lamp, and the design of dynamos and arc lamps to work on series circuits, have never been discussed. The properties necessary for success in parallel running have never been formulated. The alternating arc lamp has received even less attention. All this is apparently because some ten years ago it was the fashion to talk of arc lamps as out of date in comparison with the more modern incandescent lamp. Here we have a comparison drawn between two lights which cannot be said to compete, because neither can replace the other. The incandescent lamp got the best of the foolish battle, and the arc lamp has remained very much where it was twelve years ago. The senseless feud between the advocates of alternating and direct currents is now producing equally disastrous results. It is quite time engineers studied arc lamps seriously, designed them to suit modern distribution systems, and arranged them to burn cheap carbons without "pumping" and without getting out of order. Mr. Crompton prophesies a great future for arc lamps, and it is certainly curious that the arc is least used in the only country where the incandescent lamp is expensive. Insular prejudice—or, what is much the same thing, insular ignorance—is still extant in this country.

Brisbane.—The South Brisbane Municipal Council have accepted a tender to light the borough by electricity. About a fortnight ago, says the *Brisbane Courier* of the 27th ult., the Lighting Committee were instructed by the Council to take the matter of substituting the electric light for gas in the streets of the municipality into consideration, and they entered into negotiations with Messrs. Trackson Bros. and Messrs. Barton and White (the latter firm representing the Crompton Supply Company of Australasia). The Committee were empowered to enter into a contract with Messrs. Barton and White for three months. An agreement was drawn up, but Messrs. Barton and White did not offer to sign the contract. In the interval one of the Directors of the Crompton Company had arrived from the south, and had raised an objection to the short period the Council were prepared to allow for the supply of electric light to private establishments. The firm subsequently sent in another tender, one of the conditions of which was that the time allowed for private lighting should be extended to either five or seven years. The Lighting Committee did not consider they would be justified in conceding the terms asked for by the firm. They then consulted with Messrs. Track on Bros., who had also sent in a tender for the lighting of the municipality, and that tender was considered at a special meeting of the Council. The meeting lasted for three hours. The question arose as to whether the lighting of the borough by electricity was a matter of emergency, and it was declared to be so. It was finally agreed that a contract should be entered into with Messrs. Trackson Bros. for the lighting of the borough by electricity for three years, the number of lamps to be 250, with the option of a further term of two years upon the basis laid down in the tender.

Electric Railroad Building in the United States.—The following extract from an American "Monthly Investment Circular" may be of interest :—

An interesting feature of the growth of electric power as applied to transportation is the establishment of connecting lines between near-by cities and towns, many of such lines being designed as carriers of light freight as well as passengers. The increased economy of operation by electricity rather than by horse power, and the greatly improved service thus attained, have been amply demonstrated for purposes of street railway traffic, and the field of operation is now being enlarged in such a manner as to make serious inroads upon the local business of steam roads between prosperous adjacent points. One of the earlier inter-urban lines was that between St. Paul and Minneapolis, which has been a very marked success. The electric line between Boston and Lynn was recently acquired by a syndicate at high figures. The proposed electric road between Baltimore and Washington (40 miles) has so far progressed that bids for the road-bed construction have been invited. A line of 40 miles is projected from Springfield, Mass., to Athol, passing through several important towns and following the highways. This line, if built, will carry passengers and light freight which now goes by the Boston and Albany. The Consolidated Street Railway Company of Worcester, Mass., has applied for franchises for over 40 miles of new roads, extending to a large number of the manufacturing towns in that vicinity. The street railways of Norwich and New London, Ct., are being consolidated and it is proposed to connect the two cities by a 15-mile road, competing with the Vermont Central for this local business. Wilmington and New Castle, Del., are to be connected by a new electric line of 8 miles. An electric road, 70 miles long, is proposed from Lancaster, Pa., to Bryn Mawr. A 25-mile electric line is proposed between Harrisburg and Mechanicsville, Pa. A company has been incorporated to build an electric road of 80 miles from Northumberland to Scranton, Pa., and to furnish light, heat and power to intermediate towns. In Ohio a trolley railroad is projected about 100 miles in length, extending from Toledo to Findlay, and designed for freight as well as passengers. A company has been incorporated in New Jersey under the name of the New England Street Railway Company for the purpose of acquiring the street railways in a large number of the cities and towns of the New England States, and operating them as one great concern. It is supposed to be a part of the plan to connect many of these places by electric railways, and the scheme is one of the most extensive in this line. Another great combination has been formed designed to connect Newark, Jersey City, Elizabeth, Plainfield, Orange and other cities in New Jersey and bring their traffic to the Hudson River. A line to be operated under a new storage system, instead of by trolley, is proposed between Cincinnati and Dayton, O. It is claimed that a speed of 30 miles, and over, an hour will be practicable under this system. The most ambitious project of all is the building of an air-line electric railway between Chicago and St. Louis, concerning the construction and success of which there is much natural scepticism. These citations are given merely to indicate the constantly growing importance of electric transportation. It is a factor in the railroad situation which cannot be ignored. It is a question if this business is not being pushed too fast. The fact that electric street railways have been uniformly successful does not prove that it is wise to try to cover the country in competition with steam roads. As in all other desirable investment lines, careful discrimination is needed here. There are fields for profitable lines where towns are not far apart and traffic is heavy, but many an ambitious trolley line through long stretches of thinly populated country will come to grief. The Railroad Commissioners of Massachusetts give a warning against indiscriminate buying of electric railway securities. The last report of the New Hampshire Railroad Commission argues against the granting of franchises for electric lines along public highways connecting different towns. It says there is no good reason why steam roads should be required to buy right of way, to construct bridges and stations, and to maintain a roadbed, and electric roads be furnished these things at public expense. The report says: "We hope to see established in New Hampshire the rule that all railways which are designed to do a through business from one town to another shall keep out of the public thoroughfares, pay for the land they occupy, and build their own bridges, fences and stations." A bill will be introduced in the next Connecticut legislature prohibiting the building of street or electric railroads to parallel existing steam roads.

ELECTROMAGNETIC THEORY.—XLVIII.

BY OLIVER HEAVISIDE.

(*Continued from page 650.*)

§ 195. Next consider the effect of a conducting medium upon the total displacement. We know that the latter decreases with the time, and the law of decrease may be readily found from the theory of a single conducting plate. We found that when its conductance exceeded a certain value, the loss of displacement exceeded the original. But, in regarding the action of a homogeneous conductor upon a wave as the limit (in the gross) of that of an assemblage of parallel plates in which the conductance is localised (which process may not seem unassailably accurate beforehand, but which is justified by the results), it is easy to see that we have merely to deal with plates of such very low conductance that the loss at each is extremely small, so that the above-mentioned difficulty does not enter. Thus, let the loss at one plate be such as to reduce the initial displacement D in a wave to mD, where m is a fraction nearly equal to unity. Here mD is the sum of the displacements in the transmitted and reflected waves, the latter being very small and of the opposite sign to the initial D. As these waves separate, they reach other plates and are split anew. If these plates have each the same conductance as the first, the total mD is further attenuated by them to m^2D when the two waves become four. Next, when these four waves are split into eight by the next plates that are reached, the total displacement becomes m^3D ; and so on. These successive displacement totals decrease according to the law of a geometrical series. It follows that, in the limit, we shall have the total displacement represented by an exponential function of the time, say by

$$\mathrm{D} = \mathrm{D}_0 \epsilon^{-nt}, \quad \ldots \ldots \quad (1)$$

where D_0 is the initial value, and D what it becomes at time t. To find the value of n, we have merely to examine the form of the fraction m, observe how it depends on the conductance of one plate, and proceed to the limit by making the number of plates infinite, whilst their conductances are infinitely small. The result is that the constant n has the value k/c, where k is the conductivity and c the permittivity of the homogeneous conducting medium.

In the irrational units of the B.A. Committee this quantity is represented by $4\pi k/c$, which is, of course, nonsense, like the quaternionic doctrine about the square of a vector. They are both going to go. The above reasoning applies to any initial distribution of displacement in plane layers, instead of merely one elementary sheet. Therefore, equation (1) shows that the total displacement subsides according to the time-factor $\epsilon^{-kt/c}$. Now, this represents Maxwell's law of subsidence of displacement in a conducting condenser (apart from "absorption" and hysteresis), or of the static distribution of displacement associated with electrification in a conducting medium. We see that the law has a far more general meaning. The initial displacement need not be static, but may be accompanied by magnetic induction, and may consequently move about in the most varied manner, whilst its total amount decreases according to the static law. A homogeneous medium is presupposed, and modifications may be introduced by the action of boundaries.

Passing next to the analogous case of a magnetic conductor, in which the total displacement remains constant whilst the total induction subsides, it is unnecessary to repeat the argument, but is sufficient to point out the law according to which the subsidence occurs. If B_0 be the initial total induction, and B what it becomes at time t, we shall have

$$\mathrm{B} = \mathrm{B}_0 \epsilon^{-gt/\mu}, \quad \ldots \ldots \quad (2)$$

where g is the magnetic conductivity and μ the inductivity. The time-constant c/k of the former case has become μ/g.

Returning to the former case, it should be noted that when the initial distribution is of the static nature, unaccompanied by magnetic force, it retains this property during the subsidence. For, since the displacement subsides everywhere according to the same time-factor, its distribution does not alter relatively, or it remains similar to itself. Since, then, there is no magnetic force, there is also no true electric current. There is also no flux of energy. That is, the electric energy is converted into heat on the spot.

A considerable extension may be given to this property. If there be a conducting dielectric in which the permittivity varies from place to place, containing a static distribution of displacement, then, if the conductivity vary similarly from place to place, so that the time-constant c/k is the same everywhere, the displacement will subside everywhere alike, without magnetic force or flux of energy, and with purely local dissipation of the electric energy. For the solution is represented by

$$\mathbf{E} = \mathbf{E}_0 \epsilon^{kt/c}, \quad \mathbf{H} = 0,$$

where $\mathbf{E}_0$ is the initial electric force of the static kind, having no curl, and $\mathbf{E}$ that at time t. Both the fundamental circuital laws are satisfied, the first because the true current is the sum of the conduction and displacement currents, and the second because $\mathbf{E}_0$ has no curl and k/c is constant. If it were not constant then, obviously, the property considered would not be true ; there would be different rates of subsidence at different places, and the distribution of displacement would change, along with magnetic force, electric current and transfer of energy.

The corresponding property in a magnetic conductor requires the constancy of the time-constant μ/g. Then, whether μ and g are themselves constant or variable from place to place, a static distribution of induction subsides everywhere alike, and without the generation of electric force.

Returning again to plane strata of displacement in an electrically-conducting homogeneous dielectric, it may be inquired how the property (1) of the subsidence of the total displacement will be affected by the simultaneous existence of magnetic conductivity. This will undoubtedly affect the phenomena in detail, but will have no effect on the property in question. Similarly, the law (2) of the subsidence of total induction will not be affected by the presence of electric conductivity. That is, in general, when there are both conductivities present, and both the fluxes displacement and induction present, the total displacement subsides according to one law and the total induction according to the other, without interference. These properties have their parallels in the theory of telegraph circuits, as we shall see later.

It should be remembered that we are dealing always with matter in the gross, and not with molecules at all ; or, equivalently, we assume a homogeneous constitution of the elements of volume. Thus, when displacement subsides in an electric conductor without generating magnetic force, the possibility and necessity of which are clearly indicated by the two circuital laws, it may be that if we go in between the molecules there is magnetic force. It is, in fact, difficult to conceive how displacement in a heterogeneous medium of molecular constitution could be done away with without the generation of magnetic force, considering that the energy of the displacement is converted into heat energy.

This matter, however, does not belong to the skeleton theory of electromagnetism, but is rather to be considered as a side-matter involving physical hypotheses to account for the influence of matter upon the electromagnetic laws.

§ 196. Besides the above simple laws relating to the subsidence of the total fluxes (sometimes true for the elementary parts) there are equally simple laws relating to the subsidence of the fluxes at the front of a wave advancing into previously undisturbed parts of the medium, which sometimes admit of extension to the body of the wave. To understand this it may be mentioned first, that the front of a wave in a non-conducting dielectric is always pure ; that is, the electric and magnetic fluxes are in the wave-plane, and are perpendicular and in constant ratio. The body of the wave need not be of this pure type, owing to the change of form of the wave-front and other causes, but the property of purity always characterises the wave-front. This may be disguised in the case of a thin electromagnetic shell, when this is regarded as the front, for the shell itself may be complex. Then the mere front of the shell may be the only quite pure part. But taking cases free from this complication, we should next note that the

Hosted by Google

introduction of conductivity into the medium makes no difference in the form of the wave-front or its position at a given stage of its progress, provided, of course, that the two quantities upon which the speed of propagation depends—the inductivity and permittivity—are not altered. Now, as has been already explained in connection with the theory of a thin conducting plate, as the wave advances through a continuously conducting medium its successive layers are being continuously subjected to a reflecting process, a minute portion of every layer being thrown back, whilst the bulk is transmitted. In the body of a wave, therefore, there is a mixed up state of things. At the very front, on the other hand, there is no such mixture, for the disturbance consists wholly of what has been transmitted of the front layer. We may, therefore, fully expect that the law of its attenuation in transit is of a simple nature.

To find it, locally condense the conductance into that of any number of equal conducting plates. Let any one of these plates attenuate a wave traversing it from E to mE. If initially pure it emerges a pure wave, and passes on to the next plate, where it suffers a second attenuation—viz., to m^2E, and again emerges pure. At the third plate it becomes m^3E, and so on. The reflected portions we wholly ignore at present. The limit of this process, when the plates are infinitely closely packed and of infinitely small conductance, so as to become a homogeneous dielectric possessing finite conductivity, is that the time-factor of attenuation takes the exponential form. The result is

$$E = E_0 \epsilon^{-kt/2c}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

E_0 being the initial, and E the value at time t. The time-constant $2c/k$ is just double that of the subsidence of total displacement. Whilst, for example, the total displacement in a plane wave attenuates to, say, $\frac{1}{100}$ of its initial value, the disturbance at the wave front has only attenuated to $\frac{1}{10}$ of its original value.

The property (3) applies to the magnetic as well as to the electric force and flux. It does not apply merely to plane waves, but to any waves, because the superficial layer only is involved, and any elementary portion thereof may be regarded as plane. So it comes about that the exponential factor given in (3) makes its appearance in all investigations of waves in electrical conductors when the permittivity is not ignored. It is a more fundamental formula than the previous one with the time-constant c/k, which is the final result of the complex process of mixture of reflected waves, or is equivalent thereto.

The corresponding property in a magnetic conductor is that the disturbance at the front of a wave is attenuated in time t according to the time-constant $2\mu/g$. Thus,

$$E = E_0 \epsilon^{-gt/2\mu}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

Here the time-constant is twice that of the subsidence of the total induction. Like the former formulæ, these modified ones, (3) and (4), have their representatives in the theory of a telegraph circuit, in spite of the absence of magnetic conductance. It is replaced by something that produces approximately the same result.

In a conductor possessing duplex conductivity, electric and magnetic, their attenuative actions at the wave-front are independently cumulative, or additive. The attenuation is expressed by

$$E = \mu v H = E_0 \epsilon^{-(k/2c + g/2\mu)t}. \quad . \quad . \quad . \quad (5)$$

It is really the attenuative actions of a single conducting plate that are additive. This applies separately to every successive thin conducting layer through which the front of the wave runs, with the result (5), where the time-factor is the product of the two former time-factors of (3) and (4).

In the theory of coils and condensers, not only do we meet with the time-constants L/R and S/K, the ratios of inductance to resistance and of permittance to conductance, but also with the double values. Their ultimate origin may be traced in the theory of the effect of a thin conducting plate upon a wave.

The exponential time-factors concerned in (3) and (4), and the more complex one in (5) also make their appearance in connection with the disturbance in the body of a wave, though in a less simple manner. This will be returned to.

§ 197. Coming now to the influence of conductivity on a wave elsewhere than at its extreme front, where we have recognised that the influence is simply attenuative, the easiest way of treating the matter is not to pass from the known to the unknown, but to reverse the process and pick out the cases which theory indicates are most readily understandable. This is to be done by a process of generalisation. The theory of a conductor with duplex conductivity is, in a certain case, far simpler than that of a real electric conductor. We have already mentioned that the reflective actions of two plates, one an electric the other a magnetic conductor, are of opposite natures. The first reverses the displacement, and the second reverses the induction when throwing back a portion of the wave. The joint action of the two plates when coexistent and coincident, or the action of a single plate with duplex conductance, results in a complete disappearance of the reflected wave when the conductances are in proper ratio and the plate is infinitely thin. We then have transmission with attenuation but without reflection. This occurs, in a homogeneous medium, when $k/c = g/\mu$. Reflex action being abolished, we are reduced to a kind of propagation of unique simplicity.

To see the full meaning of this, start from any initial distributions of induction and displacement in a non-conducting dielectric. Imagine that we have obtained the full solution showing the subsequent history of the disturbances. Now, if we introduce only one kind of conductivity, we shall, with the same initial state, have a profoundly different subsequent history. Again, with magnetic conductivity alone, we shall have a course of events different from both the previous. But if we add on magnetic conductivity to previously existent electric conductivity, we shall partly counteract the distorting influence of the latter. This counteraction becomes complete when the value of the magnetic conductivity is raised so high as to produce equality of the time-constants of attenuation due to the two conductivities separately. Further increase of the magnetic conductivity will overdo the correction and bring on distortion again, though of a different kind.

Similarly, the distortion due to magnetic conductivity alone is diminished by introducing electric conductivity, and becomes completely abolished when there is enough of the latter to equalise the time-constants. Further increase brings on the distortion again, which is now of the electric kind.

When the state of balance occurs, and the distortion is wholly removed, the course of events following any initial state is precisely the same as in a non-conducting medium, but with a continuous attenuation expressed by equation (5) above specialised to suit the equality of the time-constants. That is, the time factor of attenuation is now $\epsilon^{-kt/c}$. This removal of distortion applies to every kind of wave.

This distortionless state in conducting media furnishes a sort of central basis for investigating the more recondite effects accompanying distortion. Nevertheless, its consideration would possess only a theoretical value, on account of the non-existence of the second kind of conductivity involved, were it not for the remarkable practical imitation of the distortionless state of things which is presented in the theory of telephone and other circuits under certain circumstances. If we abolish the fictitious magnetic conductivity throughout the medium traversed by the waves, we should, to have distortionless transmission, also abolish the electric conductivity. This is only to be attained by using wires of no resistance to guide the waves through a non-conducting medium. But they have resistance, of greater or lesser importance according to circumstances. Of what nature, then, is the distortion of waves produced by the resistance of a wire along which they run? The answer is, that it is approximately of the kind due to magnetic conductivity in the medium generally. On the other hand, the different kind of distortion due to electric conductivity in the medium generally remains in action, being the effect of the leakage-conductance of the insulating medium surrounding the wire, or the average effect of other kinds of leakage at distinct and separate spots along the circuit. Thus we obtain an approximate reproduction of the theory of magnetic conductivity acting to neutralise the distorting effect of electric conductivity. The time-constants μ/g and c/k become L/R and S/K in a telegraph circuit,

Hosted by Google

L being inductance, R resistance, S permittance, and K leakage-conductance. Their equalisation produces the distortionless circuit, which may turn up again later on. In the meantime I may remark that if the reader wishes to understand these things, he must give up any ancient prejudices he may be enamoured of about a "KR law" and the consequent impossibility of telephoning when "KR" is over 10,000. When pointing out, in 1887, the true nature of the telephonic problem and the absurdity of the "KR law" applied thereto generally, I predicted the possibility of telephoning with "KR" several times as great. It has since been done. In America, of course. A short time since, in noticing the KR = 32,000 reached by the New York-Chicago circuit, I further predicted that it would go up a lot more. It did very shortly after. The record is now about 50,000 (Boston-Chicago) for practical work, I believe. It means a good deal more for possible work. But there is no need to stop at 50,000. That can be largely exceeded in an enterprising country.

(*To be continued.*)

SOME APPLICATIONS OF ELECTRICITY TO CHEMISTRY.*

BY JAMES SWINBURNE.

It would be quite impossible to give any adequate idea of the applications of electricity to chemistry in three short lectures. Now that dynamo-electric machines are made which give high efficiencies, and which are low in first cost, the applications of electricity to commercial chemistry are increasing, we may truly say, every week, and the future development of electro-chemical work will be so enormous that even a bird's-eye view of the subject ought to prove interesting. It will be unnecessary to go into commercial questions; what will be attempted is a glance at the scientific basis of some of the more interesting and more important applications of electricity to chemical industry.

Most of the applications depend on the electrical decomposition of saline solutions, or electrolytes. When electricity is passed through an electrolyte it is split up into two components of which one is in a higher, and the other in a lower, state of oxidation. In the simple case, for instance, of passing electricity through water, oxygen is produced at one pole and hydrogen at the other. Again, if, for instance, chloride of copper is electrolised, chlorine comes off at one pole and copper at the other. The copper is said to be reduced, as chloride of copper, though it contains no oxygen, is considered to be in a higher state of oxidation than the original copper, because the chlorine takes the place of oxygen. Similarly, chlorine is in chemical language in a higher state of oxidation than a chloride, because it is obtained by oxidising a chloride; for instance, by treating it with sulphuric acid and manganese dioxide. These terms are, unfortunately, very loose, and it would be much better to speak of salts, and of electro-positive and electro-negative radicles, the radicles being the components of the salt that are separated by the passage of electricity. As the terms oxidation and reduction are already so extensively, though loosely, used, and as they apply also to chemical actions performed on bodies which are not electrolytes, it will be better to adhere to their use.

A glance at the work of the chemist shows that a very large proportion of his labours consists in oxidising or reducing the various substances with which he deals. Sometimes he is making changes or substitutions, but his chief work is oxidising and reducing. Here, then, we have at once the reason why electricity is becoming so important. Consider for a moment the advantage of the electrical over the chemical method. Take the case of water already mentioned. To reduce it to hydrogen it would have to be, let us say, heated in contact with iron, carbon, or something which has enough affinity for oxygen to abstract it from the water. In this case, the hydrogen is set free but the oxygen is not; it is combined with another body. Again, to oxidise the chloride some such treatment as that with manganese dioxide and sulphuric acid is necessary. By electrolysis, however, the oxygen and hydrogen, or the copper and chlorine, are produced direct without any complications and without introducing foreign substances. When it is remembered that many of the ores from which metals are obtained are oxides, and that the smelting of these consists of reduction only and is carried out in a manner which gives impure metals, and that the remaining ores are mostly sulphides, which are roasted into oxides and then reduced, it will be realised that electricity has a magnificent future in metallurgy. This is not by any means all. The important alkali industry consists of splitting up common salt into caustic soda and chlorine, and the process of manufacture, as at present carried on, is a bewildering maze of oxidation, reduction and substitution. In making alkali and bleaching powder by the Leblanc-Weldon processes, beginning with salt and pyrites and ending with caustic and chlorine, there are, taking it favourably, four oxidations, one reduction and three substitution processes. By electrolysis, salt is decomposed into caustic soda and chlorine at one operation without the aid of any other chemicals, and without any waste, loss, or by-product. Direct electrolysis of solutions of salts is by no means the only process available; fused salts can be electrolised, and aluminium is reduced extensively from its salts by this method. It is probable that sodium and potassium will soon be produced from their fused salts in the same way.

Electricity provides the chemist with still another powerful method for treating refractory substances. If electrical energy is spent rapidly in a confined space, so that the heat produced cannot escape easily, any temperature may be reached short of the melting or volatilising points of the materials employed. This is the electrical furnace, which will be dealt with in a later lecture.

The oldest, and by no means the least important, application of electricity is electro-plating. The process of electro-plating with silver, gold and nickel is so well known that it will be better not to devote the short time at disposal to their consideration, except to mention a few recent developments. Electro-plating with silver containing a small percentage of cadmium or "Arcas" plating is a recent improvement. The sulphide of cadmium is yellow, and as it combines with sulphur more readily than silver, it is said to absorb the sulphur and to form a thin coating of cadmium sulphide, which protects the silver so that it is not blackened by fumes of sulphuretted hydrogen. Prof. Silvanus Thompson strongly advocates the substitution of cobalt for nickel, as it does not tarnish so easily and does not become yellow. Mr. J. W. Swan has also recently developed processes for rapid deposition of copper for electrotype and such purposes.

The metal deposited by electrolysis is, unfortunately, in a crystalline condition, and this is frequently a source of trouble. As a striking example of abnormal molecular state, Gore's explosive antimony may be mentioned. This is electrolytically-deposited antimony, in which the particles appear to be under constraint, or in a state of unstable equilibrium. If the metal is touched with a hot wire it undergoes an internal change by which it developes so much heat that it rises to a high temperature. A rod of tin which has been thickly coated with a deposit of antimony can be melted if the antimony is discharged. The metal here almost seems to be in an allotropic state, as in the well-known cases of plastic sulphur, or iodide of mercury. Several metals are deposited in trees or masses of fine crystals, which are so bulky that they cannot be dealt with practically. This is the case, for instance, with lead in acid solutions. In alkaline solutions the deposit is closer. Many of the more easily oxidised metals, such as sodium and potassium, cannot be deposited by electrolysis from aqueous solutions, as the metals themselves decompose water. It is curious that they can be deposited into mercury, forming an amalgam. The amalgam itself will, in some cases, decompose water, but more slowly, and the attraction of the mercury for the sodium or potassium seems to partly counteract the tendency to form the hydrate. The affinity of mercury for these metals is so

* A course of three "Tyndall" lectures at the Royal Institution.

Hosted by Google

strong that they flash when they make contact with mercury. It is a remarkable fact, however, that in some cases the metal seems to be deposited not in the mercury but on its surface, amalgamation taking place afterwards. This can be seen easily in the case of lead. Lead trees can be formed on the surface of the mercury, but the least vibration will cause the mercury to amalgamate the tree and draw it in. A slender tree a few inches long will be drawn in, and amalgamated so quickly that the eye cannot follow the motion. The amalgam of aluminium is instructive. When it is exposed to the air, the aluminium oxidises and produces a sort of white fur of alumina. The combustion of the aluminium is sometimes rapid enough to cause considerable rise of temperature. This shows that aluminium does not really remain clean and bright, but that the surface oxidises and a thin protective layer of oxide is formed which prevents any further action. It is this layer which prevents the metal being soldered easily, especially as there is no flux which will dissolve alumina without attacking the aluminium. In the case of amalgamation, the oxide does not protect the metal from further action, as it cannot adhere to the surface of the mercury; the oxidation, therefore, goes on till the aluminium is all oxidised. Electro-deposition is now largely practised in copper refining. Crude copper is cast into anodes and placed in vats of sulphate of copper with thin sheet copper cathodes. The copper is dissolved off and deposited on the thin cathode plates. The silver and gold fall to the bottom, with various impurities, such as antimony and arsenic. The silver and gold are thus completely separated, and the crude copper is changed for the much more valuable pure product. Lead would be treated in much the same way, if it were not that it is apt to deposit in a loose spongey form, instead of in a coherent mass. Electrical processes are also coming into use by which many of the ores are merely roasted to convert them into oxide, and then dissolved in acid, the solution being electrolised to yield the metal in a state of almost perfect purity.

One of the most important applications of electricity will be, as already hinted, in the manufacture of soda and bleaching powder direct from salt. If a solution of salt is electrolised, caustic soda is produced at the cathode and chlorine is given off at the anode. The chief difficulty is to find a good material for the anodes. No metal will do, for all metals would be attacked by the chlorine, chlorides being formed. Carbon is the only material available. It is attacked to some extent, not by chlorine but by oxygen; but electrolytic soda has now reached a stage in which this last difficulty may be said to be overcome by using a form of carbon which is so cheap that its corrosion does not much matter. At Snodland there is a model caustic plant at work which has been making soda and bleaching powder by the ton for some time. The solution of caustic made by the process described contains a great deal of undecomposed salt, which is a drawback, and to overcome this difficulty a very ingenious arrangement has been recently proposed by Kellner and by Vautin. As has just been explained, sodium can be deposited into mercury, and this property is utilised in a curious way. The anode is in one chamber and the cathode in the other, and the two are separated by a partition of mercury. Two complete cells are thus really produced. In the chlorine cell the carbon is the anode and one side of the mercury is the cathode. Sodium is deposited into the mercury. In the caustic compartment the other side of the mercury forms the anode, and the sodium is dissolved out hydrogen coming off at the cathode. By this means the caustic is obtained pure, without the admixture of salt.

If, on the other hand, the caustic is allowed to mix with the rest of the liquid, chlorine is no longer given off, but the salt is changed to hypochlorite of soda. This may be used for bleaching. If the operation is now carried on at a higher temperature, chlorate is formed. Chlorate of potassium is now manufactured on a large scale from the chloride in this way.

So far, we have chiefly considered the commercial applications of electricity. It must be remembered that it was by electrical means that sodium, potassium, magnesium, lithium, strontium, barium, and calcium were first produced. All these metals, with one exception, were first isolated by Sir Humphry Davy, Professor of Chemistry at the Royal Institution. More recently, electrolysis has been used in the endeavour to isolate fluorine, by electrolising fluoride in a vessel made entirely of a fluoride. In chemical analysis, again, electricity can be a great help. By its means metals can be separated which are troublesome to deal with by purely chemical methods. As an example of the application to analysis, testing for arsenic in forensic cases may be mentioned. It has been usual to evolve hydrogen from zinc, the hydrogen being contaminated with arseniuretted hydrogen if arsenic is present. Unfortunately, zinc is apt to contain arsenic, and where the life of a human being may depend on the result of a test it is most important to avoid all chances of error. The hydrogen should, therefore, be evolved electrically from a platinum plate, so that at least one source of error is eliminated.

One of the most complicated branches of the study of chemistry is the formation of dye stuffs. Oxidation and reduction can frequently be carried out by electrolysis without introducing special oxidising and reducing agents. Here, then, is a wide field for scientific research. Dr. Goppelsroeder has done a great deal of work on the subject, but it is well worthy of further attention. Whether such a process is valuable commercially is a matter of doubt, but it provides the chemist with a new method of investigation, and may lead to important discoveries in this branch of organic chemistry.

Electricity also derives benefits from chemistry. Faraday discovered that the quantity of metal deposited was strictly proportional to the quantity of electricity passed through the solution. This has provided electricians with a very exact method of measuring quantities of electricity. Lord Rayleigh has made very careful determinations of the exact weight of silver deposited by a unit quantity of electricity, and this measurement now serves as the practical standard for the measurement of electricity, and hence of electric currents.

[Various experiments were made during the lecture, showing the decomposition of water, the translation of copper from one pole to the other, the production and properties of sodium and aluminium amalgams, the production of caustic and bleach, the production of oxygen and hydrogen by electrolysis, and the production of aniline colours.]

A COLLECTOR OF ATMOSPHERIC ELECTRICITY.*

BY L. PALMIERI.

The apparatus is based on the principle that as a conductor is raised in the open air it collects positive electricity (in ordinary weather), and that then after discharge it collects negative elec-

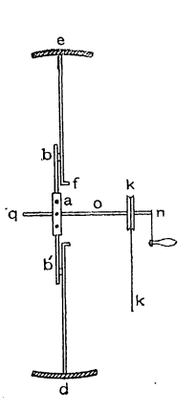

FIG. 1.

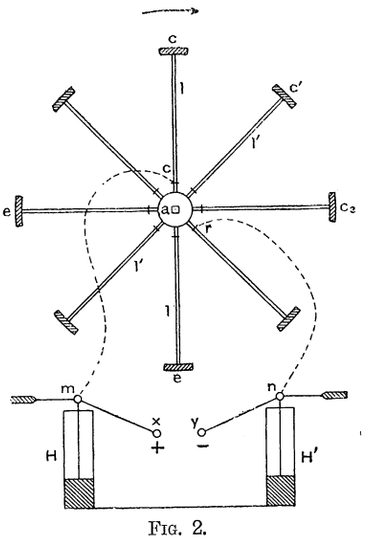

FIG. 2.

tricity as it descends. Since 1850, the date at which I undertook the study of these phenomena conjointly with those of the ascending and descending liquid vein and others, again, which I called

* From *La Lumière Electrique.*

Hosted by Google

phenomena of approach and recession, I conceived the idea of constructing a rotary electrical machine which became a source of electricity on fine, calm days. I made an entirely rough piece of apparatus, which is shown in several editions of my "Leçons de Physique," but it was always my intention to give it a convenient form and to add a suitable condenser. It is this rough piece of apparatus which is shown diagramatically in the accompanying illustrations.

Let *a* (Figs. 1 and 2) be a modern disc, upon the circumference of which are fixed eight insulated rods *b b'* (Fig. 1). These rods carry an equal number of conductors *l l'*, terminated at the top by narrow strips *c c'* of any convenient length; at the bottom the rods are terminated by little elbows *f*. Both wheel and spokes can be made to revolve rapidly round the axle *q n o* (Fig. 1) either by means of a handle or an endless cord *k*. A spring or strip of metal touches the projection *f* of each spoke as it reaches a vertical position, and a second one presses against the spokes as they come to the diametrically opposite position, so that positive electricity is collected at *c* and negative at *r*. At H and H' are placed two Leyden jars similar to those used in the Toepler and Holtz influence machines, *x* being the + terminal and *y* the − terminal of the machine.

Such is the collector in all its simplicity. In this note I only wished to describe its principle, and will say something at another time about the effects it enables one to obtain.

THE FUTURE OF PLATINUM.*

The fact that one of the greatest electric light companies has introduced a lamp that contains no platinum, the use of which has been considered indispensable, makes pertinent the query: What will be the future of this metal?

Since the introduction of the incandescent electric lamp in 1880 the consumption of platinum, not only in the United States, but also in Europe, has increased rapidly, although improvements made from time to time have greatly reduced the amount used in each lamp. In 1886-7 the Edison 16-c.p. lamp contained one grain, and the Sawyer-Mann lamp two grains; at present the Edison lamp contains but one-seventh of a grain, and the new Sawyer-Mann lamp none at all. In England the Edison-Berliner lamp, and in Germany the Siemens-Halske lamp have likewise had the amount of platinum reduced to a minimum, owing, as in this country, to the use of a shorter wire of a smaller diameter. Notwithstanding this, however, the gross amount of platinum used in this country and Europe in the manufacture of electric lamps has steadily increased from nothing in 1880 to about 55,000oz. in 1892. If the new Sawyer-Mann lamp should prove to be a success, of which, however, there is yet no proof, it might eventually replace all the other kinds of lamps now in use, and consequently this particular demand for platinum would cease.

On the other hand, however, it is to be observed that all the manufacturers of incandescent lamps have large plants already established, and that the amount of platinum used per lamp has been reduced to a minimum, so much so that its value forms less than 5 per cent. of the value of the lamp. Consequently it is quite probable that platinum will continue to be used in electric lamps, and that the amount so used will continue to increase with the growth of the industry.

There are, moreover, two other uses for platinum, which are even more important than its use in electric lighting, namely, the construction of stills for the concentration of sulphuric acid and the wires by which artificial teeth are firmly fastened to a plate. The amount used for stills varies widely from year to year, being greatly dependent upon the number of new plants started each year, but it has been estimated that the average amount so used during the last few years is about 80,000oz. The manufacture of sulphuric acid is bound to increase, and although glass concentrating vessels are now being used to some extent, it is believed that this industry will continue to supply a constantly increasing demand for platinum. For dental purposes platinum will always continue to be used, being the only metal which possesses the required properties of infusibility, ductility and strength. In the United States 35,000oz. and in England 25,000oz. are annually used in this industry, and this amount will probably increase at the rate of 2 or 3 per cent. per annum. The other uses of platinum, such as chemists' crucibles, jewellery, plating, &c., consume about 20,000oz. annually, making the entire consumption about 215,000oz. or 6,680 kilos. Of this amount from 30 to 40 per cent. is old or scrap platinum, which leaves from 4,000 to 4,676 kilos to be annually supplied by the mines.

For many years the Siberian Urals have supplied the greater part (92 per cent.) of all the platinum used in the world, but it is questionable whether its output can be maintained at its present high level for many years. According to the official statistics of the Russian Department of mines, the output of platinum in that country reached its maximum, 4,400 kilos, in 1887, following which it dropped to 2,700 kilos, and so remained until 1891, when, owing to the abnormally high price of the metal, the production amounted to 4,226 kilos. Many of the old placers are now worked out, and it is believed that the above figure represents the maximum possible output of the country. If, then, the demand should continue to increase, as seems possible, it will be necessary to look for other supplies of the metal. Next to Russia the most important sources of platinum, so far as known, are Colombia, British Columbia, and the United States. At present Colombia produces but 125 kilos of platinum per annum, entirely the result of native washing. The platiniferous area, although of low grade, is, however, quite extensive, and in part suitable for hydraulic mining. A considerable amount of American capital has already been invested there, and it is quite probable that Colombia will become an important producer of the metal. The only platinum deposits of importance in British Columbia are found on the Talameen River. Recently a company has been formed to hydraulic these gravels, but so far the output has been small. The total production of British Columbia is about 65 kilos. In the United States much prospecting has been done to find platinum in paying quantities, but so far without success, and up to the present time all the platinum produced has been incidental to the production of gold from various auriferous gravels in California and Oregon. If the laws prohibiting hydraulic mining in California should be repealed, that State may become a more important producer of platinum.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, April 21st.

INSTITUTION OF MECHANICAL ENGINEERS.

7.30 p.m. Ordinary General Meeting.

BALLOON SOCIETY.

8 p.m. Address at St. James's Hall: "Telephonic Communication in the United Kingdom," by A. H. Hastie.

OLD STUDENTS' ASSOCIATION.

8 p.m. Smoking Concert at Masons' Hall Tavern.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Possible and Impossible Economies in the Utilisation of Energy," by Prof. A. B. W. Kennedy, F.R.S.

SATURDAY, April 22nd.

ROYAL INSTITUTION.

3 p.m. Tyndall Lecture (2): "Some Applications of Electricity to Chemistry," by James Swinburne, M.Inst.E.E.

TUESDAY, April 25th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed: "Steam-Engine Trials," by the late P. W. Willans, M.Inst.C.E.

WEDNESDAY, April 26th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "The Optical Correction of Photographic Perspective," by H. Van der Weyde.

THURSDAY, April 27th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Atmosphere," by Prof. Dewar, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Paper to be further discussed: "The Distribution of Power by Alternate Current Motors," by Albion T. Snell, M.Inst.E.E.

FRIDAY, April 28th.

PHYSICAL SOCIETY.

5 p.m. Paper to be discussed: (1) "Experiments on the Viscosity of Liquids," by Prof. J. Perry, J. Graham, and L. W. Heath. Paper to be read: (2) "On Luminous Discharges in Electrodeless Vacuum Tubes," by E. C. Rimington.

INSTITUTION OF CIVIL ENGINEERS.

7.30 p.m. Students' Meeting. Paper to be read: "Fire-Risks of Electric Lighting," by H. W. Handcock, Stud.Inst.C.E.

ROYAL INSTITUTION.

9 p.m. Evening Discourse. "Transmission of a Nervous Impulse," by Prof. F. Gotch, F.R.S.

SATURDAY, April 29th.

ROYAL INSTITUTION.

3 p.m. Tyndall Lecture (3): Some Applications of Electricity to Chemistry," by James Swinburne, M.Inst.E.E.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not late than Thursday, 6 p.m.

Hosted by Google

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.

Editorial, Publishing, and Printing Offices :

SALISBURY COURT, FLEET ST., LONDON, E.C.

Telephone No. 2714. *Telegrams :* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.* "THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

ew Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" SERIES *at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.

The same in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. [*Nearly ready.*

MATHEMATICS IN PLACE AND OUT OF PLACE.

Mathematicians in search of new pasture, and practical men anxious to see what will happen when the "professor" is eliminated, should peruse a Paper on transmission of power, recently read before the National Electric Light Association by Mr. L. B. STILLWELL. "We may conveniently construct an algebraic skeleton," says the author, and he forthwith proceeds to do so. Whether this skeleton is to be kept in a cupboard, and only taken out at Institution meetings from which the professors will have already been eliminated, we are not informed. Here is the skeleton, or a small part of it:—"Fh—First cost of hydraulic plant, including turbines, dams, flumes, &c. Ph—Percentage covering interest upon and maintenance of hydraulic plant. Oh—Cost of oil and waste per annum for hydraulic plant." And so on, and so on. Then we arrive at the following mathematical equation, which, at first sight, we took to be a chemical equation in which iron and carbon, oxygen and nitrogen, and several unknown elements—which, doubtless, were the undiscovered members of MENDELEJEFF's celebrated cycles—had got considerably mixed up :—"PbFb + Cb + PhFh + Oh + Ch + AN + PeFe + Oe + Ce + PlFl + Cl = annual charges." "And now," continues the author, "what have we accomplished?" What, indeed? As a piece of anatomical mathematics this cannot compare with the efforts of the man who can cover the Institution blackboard with formulæ three times, before members have had time to get their pencils out of their

Hosted by Google

pockets; but as a piece of practical intelligence, it is a mere string of laboured nothings, calculated to "amaze the unlearned and make the learned smile." Let *Sh* be the shovel at the station, *Sw* the switchboard, and so on; then the equation to the station is $Sh + Sw + MeN + BeEr + BaC^2y$ + &c., which is a parallel piece of mathematics.

If electrical engineering cannot get along without mathematical treatment, then, *pollice verso*, let the mathematician live, and let us employ him to do the necessary work. But if, forsooth, it can, where is the advantage in this spurious semblance of mathematical form, which is the mania of some un-mathematical men? The pressing of mathematics into places where they are not needed, is as foolish as their exclusion from places where they are essential. Undoubtedly, there is an unfortunate tendency now-a-days to overburden every branch of electrical work with mathematics, to the detriment of practice. Other subjects, other industries, might equally well be mathematically treated. We have seen a series of elaborate equations, involving trigonometry and the theory of impact and elasticity, explaining a game of cricket; and it would be quite possible to write a book full of triple integrals and slant coefficients in three dimensions, to explain the operations involved in carving a statue. Mathematical form, unless there be in it the breath of practical life, is, indeed, a skeleton; and it would be labour ill-spent to try and galvanise it into living activity. There is not the least objection to the application of mathematics to cricket; but they remain mathematics, they do not become cricket. Prof. TAIT has indeed not only applied mathematics to golf, but has done much better service in applying golf to mathematics, and with most interesting results. But these results were no longer within the province of golf; they formed a valuable contribution to our knowledge of elastic bodies and impact. To deny that mathematics are essential to progress in the higher branches of engineering, is to confess ignorance of those branches; but to burden elementary work with abstruse calculations and with pedantic definitions, is likely to bring about contention between the practical man and the theorist. A pedant is all very well in his place, but he should not come into the workshop and snub the man at the vice.

A distinction should be observed between accuracy of elementary knowledge, and high theoretical attainments. It is important that every engineer should have exact and clear ideas as to the relations between force, power, work, and energy, and the electrical engineer must be familiar with other electrical relations. These elementary laws have an apparent connection with mathematics, because mathematicians have defined them. But the mathematics of Ohm's law go no farther than the rule of three. If some of the simple facts of engineering and of electrical science could be divested of the mathematical garb in which professors delight to clothe them, the beginner would advance with much less hesitation. He is too often presented with a fact swathed in algebraical attire, bound with many a hard and knotted formula, and decked with streaming expanded terms, tasselled at the end with "+, etc." He ultimately makes acquaintance with the fact itself, and this acquaintance continues long after the mathematical millinery has been discarded by the mind.

A sailor has a good deal to learn before he need trouble himself about taking lunar distances; and a soldier must be familiar with squad drill before he makes an acquaintance with brigade drill, and he may do excellent service as a tactician without aspiring to strategical accomplishments. Every French soldier is told that he carries a field-marshal's *bâton* in his knapsack, and, with hardly more sense of fitness, young engineers and electricians are encouraged to equip themselves with a mathematical armoury such as might enable them, if they had the wit, to take a hand in original research of a high order. That is where the waste and the pedantry come in. Theory, and, if need be, mathematics, in healthy co-operation with practical work, are to-day essential for real progress. The rule-of-thumb man progressed, it is true, but not fast enough for to-day. The ready mathematician, on the other hand, is apt to ignore essential conditions and to rush on wildly with loose assumptions, conjectural data, and vague hypotheses, imagining all the time that he is an engineer.

THE CONSTRUCTION AND USES OF PROJECTORS.*

The great modern development of the projector is due to the extensive use which will be made of it in both naval and military war operations, where the power of rendering visible distant ships or bodies of men will be of enormous value. The most essential part of a projector consists of an optical means whereby the rays of some source of light are collected by reflection or refraction, and projected in the form of a beam towards the distant object which it is desired to illuminate. The efficiency of a projector depends (1) on the size of the "useful angle"—that is, the angle contained by the rays which are reflected or refracted by the extreme edges of the projector, this angle being a measure of the amount of the radiation which is effected by the projector; (2) on its capacity to transmit the radiation collected with the minimum of loss to the object to be illuminated; (3) on the nature of the source of illumination. The most important point is to determine the efficiency of the various optical devices possible with respect to the two former of the above considerations.

The original use of projectors was for lighthouses, and the most obvious method was employed, namely, the use of parabolic mirrors of metal, these mirrors converting the rays falling on them into a parallel beam. The objections to these mirrors were firstly, difficulty of construction, secondly, the fact that the polish is soon lost, and thirdly, the low reflecting power. Researches by Prof. Potter gave a loss of 31 to 35 per cent. for "mirror-metal," and Stephenson found for polished silver and an angle of reflection of 45° that the loss was about 44 per cent. Silvered glass is much better, but it was found impossible to make sufficiently accurate parabolic mirrors out of glass. Later on spherical mirrors were used instead of parabolic, which led to the difficulty that the "useful angle" was small; for if the angle used be too great, the dispersion becomes so great that no advantage is obtained.

Fresnel was the first to introduce great improvements in lighthouse apparatus; his system has been applied also to projectors. A convex lens forms an admirable means of refracting rays coming from its focus in such a manner as to forward the rays in an approximately parallel beam so long as the diameter of the lens is small compared with the focal length; but it follows that only a limited proportion of the radiation can be utilised. If the useful angle be increased, the spherical aberration begins to become important and destroys the parallelism of the beam, and in addition to this the light becomes more split up into a spectrum, and the absorption increases in consequence of the increased thickness of glass. In order to avoid these drawbacks, Fresnel built up his lenses of concentric rings, and he surrounded these in addition with a system of completely-reflecting prism rings, in order to collect the light falling outside the lenses as well. In this manner he was able to diminish the spherical aberration by choice of suitable radii of curvature, and the absorption in consequence of the diminished thickness of glass. The total reflection prisms also constituted a most valuable reflecting device; but in spite of these improvements, which still make the Fresnel apparatus the best for lighthouse work, the instrument is not entirely the most suitable for projector work in view of later inventions. It is difficult to make the

* Abstract from a Paper presented to the Verein Deutscher Ingenieure by F. Nerz.

Hosted by Google

glass rings so exactly that the foci of all are coincident, and they still retain spherical and chromatic aberration, and if the light gets displaced from the focus the reflected and refracted rays deviate in opposite directions from parallelism with the axis, and thus a considerable diminution of intensity is produced—*see* Fig. 1.

A great step forward was made in the construction of projectors when Mangin showed that in spherical concave mirrors the deviation from parallel reflection could be almost entirely eliminated, if the inner surface has its centre of curvature nearer the mirror than the outer and reflecting surface (Fig. 2). By making it thus lenticular in form, the ray which falls on the mirror and is reflected by its convex side is

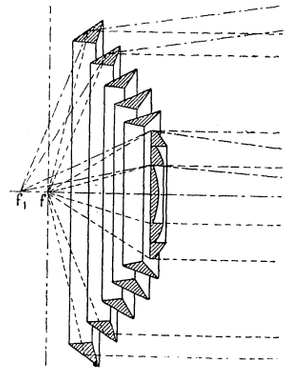

FIG. 1.

refracted at the concave surface by an amount which can be made, by suitable adjustment of the magnitudes, to very nearly compensate for the loss of parallelism by spherical aberration of the reflecting surface. The law was determined by Mangin, who found that the spherical aberration could be considered as eliminated when the diameter of the mirror was not greater than its focal length. In Fig. 2 is shown a mirror constructed on this principle in 1876; the radii were 120·0 centimetres and 160·0 centimetres for the concave and convex surfaces respectively, and the focal length was 101 centimetres. This mirror possessed the property of reflecting light emitted at its focus in a parallel beam in the highest degree up to that date attained. On the other hand on account of the great focal length, it could only use a source of illumination to a certain limited extent, its "useful angle" being about 60°. The next improvement made by Mangin

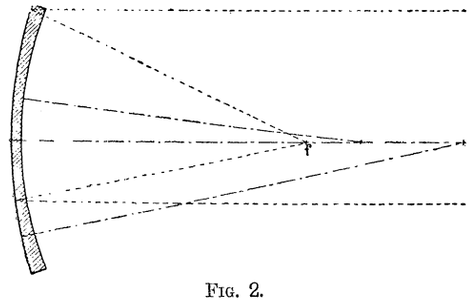

FIG. 2.

and Messrs. Sautter, Lemonnier and Co. was to put lenses between the light and the mirror, and the useful angle was thus increased to 100°; but the improvement was not very practical and was soon given up, the focal length was reduced by choice of suitable glass, and the makers contented themselves with an approximation to the law given by Mangin.

Tschikolew, of St. Petersburg, was working at the same time on reflectors for projector work and returned to parabolic mirrors; but since these could not be constructed whole out of glass, he built them up of spherically-ground rings, whose centre of curvature lay on the point of intersection of the axis with the radius of curvature of that piece of the parabola which they were intended to replace; while Siemens and Halske attempted to improve on these by making the two centres of curvature as nearly as possible coincident. The construction of such mirrors is a matter of considerable difficulty; and they have, in common with the Fresnel apparatus, the drawback, that the foci of the component parts are not easily made coincident, and further, that at the joints considerable portions of the mirror are always rendered useless; and in consequence of these defects these mirrors, though they surpass the Mangin type in the proportion of the light reflected, are inferior in general utility.

The first rival to the Mangin mirror which really surpassed it was that of Schuckert, who in 1886 succeeded in evolving, in common with Prof. Munker, a process for making parabolic mirrors in glass out of one piece, and thus practically solved the question for all time.

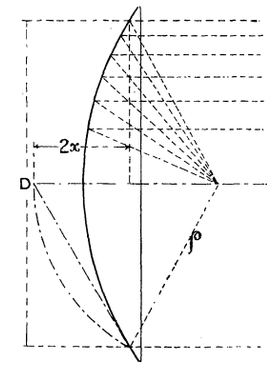

FIG. 3.

Let us consider first a luminous point in the focus of a true parabolic mirror; all rays falling on the mirror will be reflected in a direction parallel to the axis (Fig. 3). If the light is of the intensity J, then the amount of light gathered by the mirror is $= 4\pi J \rho x$; where ρ is the radius vector of the edge of the mirror, and $2x$ is the subtangent of the corresponding point on the parabola (*see* Fig.). The light so gathered by the mirror would be reflected as a perfectly cylindrical beam, and in a non-absorbent medium would travel to infinity without any diminution of intensity; at any given distance a circle of the size of the mirror would be illuminated, and if any object were brought into the beam, a true shadow picture would be projected to any distance. If the focal length be made shorter, the light can be taken up

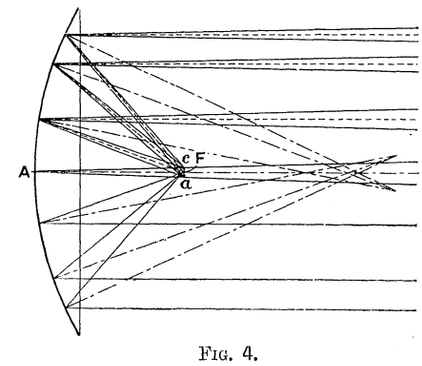

FIG. 4.

by a mirror of smaller diameter, and consequently since the area of the beam would be diminished, the intensity of illumination in it would be increased; but, of course, all this applies only to a perfectly parabolic reflector. Both Mangin mirrors and those constructed of spherical rings give, in consequence of their spherical form, a deviation from parallel reflection, and make a conical instead of a cylindrical beam, which produces a diminution of intensity with distance proportional to the increase in the area of the beam. A source of illumination confined to one point does not exist, and has no practical value. Even were it possible to recognise objects 1,000 yards distant, of which a surface equal to that of the mirror was illuminated, and if this surface could be sufficiently examined in one second, it would take about two hours to examine the whole horizon.

Hosted by Google

Every source of light has sensible dimensions. Suppose a spherical luminous body of intensity J in the focus of a parabolic mirror, then the light falling on the latter is

$$L = 2\pi J r h = 2\pi J r^2 (1 - \cos \phi/2) = 4\pi J r^2 \sin^2 \phi/4,$$

where r is the radius of the luminous sphere, and ϕ is the angle made by the rays falling on the edges of the mirror, or what we have called the "useful angle."

The average intensity (J_m) of the light measured at the mirror is given by

$$J_m = \frac{4\pi J r^2 \sin^2 \phi/4}{\rho_x^2},$$

where ρ_x is the average radius vector of the parabola.

If the source is not a sphere, but only a portion of one, and if the piece which enters into our calculation has the surface of diameter $d = a\,c$ (Fig. 4), and if f be the focal length of the mirror, then those rays which coincide with the radii vectores are reflected parallel to the axis, and the angle included between the rays aA and cA is a measure of the deviation from parallelism produced by the extension of the source of light, and gives the amount of (theoretical) dispersion, or the "illumination-angle" for a given source of illumination. The light is similarly dispersed at all points in the mirror, but the angle decreases as the distance from the centre increases; every point produces a cone of light whose axis lies parallel to that of the mirror. As all the axes of the cones lie in a cylinder whose diameter is that of the mirror, but the surfaces of the base of the cones at any distance have different diameters, the illumination produced by a projector must be most intense in the centre and fall off towards the sides. Since the several light rays can only at a considerable distance from the mirror be considered as coming from a point, but near it cross one another in endless number, objects placed near the projector cast no shadow, and the sharpness of the shadow increases with the distance. The largest angle of divergence of the light rays after reflection is called in this Paper the "angle of illumination," and is given by the formula

$$\tan \alpha/2 = d/2f.$$

At a distance e from the projector (e is supposed to be relatively large), a surface is illuminated whose diameter is

$$F = ed/f,$$

and this surface, if the mirror absorbs no light, is illuminated by the amount of light

$$L = 4\pi J r^2 \sin^2 \phi/4.$$

If there were parallel reflection, the surface illuminated would be

$$F = \pi D^2/4.$$

where D is the diameter of the reflector. Now the intensity of illumination J_2 of the field is diminished in the ratio of the squares of the diameter

$$D^2/F^2; \text{ and hence}$$

$$J_2 = \frac{4\pi J r^2 \sin^2 \phi/4\, D^2}{\rho_x^2 F^2}.$$

If for ρ_x we substitute its value

$$\rho_x = \frac{2f}{1 + \cos \delta/2} = \frac{f}{\cos^2 \delta/4},$$

where δ is the angle made by the average radius vector with the axis, and also for F^2 the value $\frac{e^2 d^2}{f^2}$, we have

$$J_2 = \frac{4\pi J r^2 \sin^2 \phi/4\, D^2 \cos^4 \delta/4}{d^2 e^2}.$$

If the surface of diameter F were directly illuminated by a similar source of light, no mirror being used, then the intensity would be

$$J_3 = \frac{4\pi J r^2 \sin^2 \phi/4}{e^2},$$

and the ratio of J_2 to J_3 gives a measure of the increase in illumination due to the projector (or what we may call its "ratio of intensification"); in this case

$$J_2/J_3 = D^2/d^2 \cos^4 \delta/4.$$

If the useful angle is the same for different sizes of mirror, then $\cos^4 \delta/4$ is a constant, and the intensity of illumination attained with such reflectors at any given distance is proportional to the square of the diameter of the mirror.

From the equation,

$$L = 4\pi J r^2 \sin^2 \phi/4,$$

which gives the amount of light gathered by the mirror, we see at once that the parabolic form surpasses the Mangin type, which has a longer focal length and consequently smaller useful angle. Comparing two mirrors of equal diameter of 60 centimetres, the Mangin form having a focal length of 42 centimetres and the parabolic reflector of 25 centimetres, the useful angles are 83° and 124° respectively; and this gives the amount of light gathered by each as 1 : 2·11; the parabolic mirror gathering, therefore, rather more than twice as much light.

(To be concluded.)

THE DISTRIBUTION OF POWER BY ALTERNATE-CURRENT MOTORS.*

BY ALBION T. SNELL, MEMBER.

Multiphase alternate-current working, although demonstrated at the Frankfort Exhibition, has not yet found favour either in England or America; but on the Continent the Drehstrom has been used with success for several important schemes, and larger applications lie in the near future. It has been pointed out, with justice, that multiphase alternate currents offer no real advantage in comparison with single-phase ones for merely the transmission, as distinguished from the distribution, of power. It is, perhaps, for distribution proper—*i.e.*, where a number of motors, varying in size, and lying over an extended area, have to be supplied from a common and probably distant source of power—that the multiphase systems find their field of usefulness. The object of this Paper is to discuss the various alternate-current motors now in the market, and, perhaps, to see how far they lend themselves to a system of distribution in which the principal conditions of supply may be stated as follows:—Firstly, the pressure in the transmission mains must be as high as possible; secondly, the pressure must be maintained fairly constant at the centre of distribution; thirdly, the pressure at the motor and lamp terminals must be comparatively low; and fourthly, the system must admit of lighting all over the area of distribution by the use of proper converters. These points are by no means easy to obtain, even singly, and when they must be concurrent the difficulty is much enhanced.

1.—*Single-Phase Synchronous Alternate-Current Motors.*

Single-phase synchronous alternate-current motors have been used since the memorable experiments at the North Foreland in 1884, but comparatively little progress has been made in their application to general commercial purposes; and the reason for this probably lies in the fact that the synchronous system is practically limited to a single pair of machines, for the starting of the motor by auxiliary power is not a prohibitive objection with one large machine, although out of the question with a number. On the other hand, the high efficiency of synchronous motors and their perfect regulation of speed with varying loads renders them especially suitable for a variety of purposes; and no efforts have been wanting on the part of scientists and engineers to place a self-starting single-phase motor in the market, but hitherto without success. It will serve no useful end to describe in detail all the various attempts, but the limiting conditions may be best gauged by a consideration of the difficulties involved, and by a few typical examples showing the directions in which solutions have been tried.

The following peculiarities are found in alternate-current working with single-phase synchronous generators and motors:—(*a*) The dynamos are always separately excited. (*b*) The motors are usually separately excited in order to save the complication of commutators. (*c*) The motors must be raised approximately to the speed of synchronism before the dynamo circuit can be closed. (*d*) The torque on any motor must not exceed a certain value, or the machine will stop. (*e*) The current lags behind the pressure by an angle which is a maximum when the motor is running light; and there may be a relatively large idle current, which, though representing little energy at the motor, causes a serious loss in the supply mains and dynamo armature. (*f*) Motors must be designed not only with reference to the pressure of supply, but also with regard to the

* Paper read before the Institution of Electrical Engineers, April 13th.

Hosted by Google

frequency of the current, and hence are only suitable for working on particular circuits; and (*g*) alternate motors, excited by either a direct or by a single-phase alternating current, have dead points in each period of alternation.

The earliest attempt to meet these conditions was by laminating the field-magnets of an ordinary direct-current motor and modifying the winding so as to make the self-induction as small as possible. The results were not successful. With shunt windings it is found to be practically impossible to excite the magnets excepting with large currents and few turns of wire, and even then, owing to the difference of phase between the field and armature currents, the torque is insignificant compared with the current used, and the dead points may involve difficulties. The series winding is better, but still useless for commercial requirements; for though, by carefully adjusting the windings it is possible to obtain a smaller lag, the weight output is still very small and the dead points remain. The loss by hysteresis in each case is so great as to be probably prohibitive, even neglecting the other objections. The crux is the frequency. This would, most likely, have to be reduced to something of the order of 20 ∿ per second, and such a current would be useless for lighting, and would largely increase the difficulty from dead points. Indeed, from this aspect the frequency should be high and the armature heavy enough to act as a fly-wheel. The author has made a number of experiments in this direction, and finds that the eye can easily detect 30 ∿ per second, and he believes from this cause it would not be expedient to work at less than from 40 to 45 ∿.

Another method involves the transformer principle, but is really only applicable to small machines. It originated with Mr. Jacobi, when one of the author's assistants, and a few motors were designed by them conjointly. With this type the armature is wound in the usual way, drum or cylinder, and has a collector of the ordinary type. The field cores are laminated and wound with two windings, one of which is coupled to the supply mains and the other connected across the armature terminals, thus forming a secondary circuit. Such a motor gives a considerable torque, is self-starting, and has probably an efficiency of 60 per cent. in 1-H.P. machines. It has dead points in each alternation undoubtedly, but they are not very apparent. The chief difficulty is that owing to the configuration of the iron of both field and armature, and the air gap, the number of lines of force passing through the two circuits is not the same; and, moreover, there is a considerable lag between the primary pressure and current. And also, which is equally important, the primary and secondary currents are not in phase. With small armatures, having few turns per coil, the sparking is little, the best results being obtained when the axis of the armature field is at 90deg., or thereabouts, to that due to the exciting current. The armatures may advantageously be wound with two circuits so as to avoid short-circuiting coils beneath the brushes.

2.—*Use of Condensers.*

The next step in alternate motor design was the attempt to balance the self-induction of the shunt-wound field magnets by a condenser, placed in series with the windings. If the condenser be correctly chosen for the frequency and the capacity of the circuit, its E.M.F. will theoretically be equal and opposite to the counter E.M.F. of the magnets, and so the exciting current will only have to be driven against the ohmic resistance of the winding, and moreover the pressure and the field current will be in phase. The armature has but small self-induction, and so its current will be also nearly in phase with the field current, and the maximum magnetism in field and armature will occur at approximately the same instant of time. Therefore the energy absorbed by the motor can be very nearly gauged by the product of the number of volts and amperes. In practice, owing to the armature reactions, the condenser will most likely not exactly counteract the counter E.M.F. at all loads. And again, even assuming such machines to be commercially practicable, they would only be suitable for one periodic time. If condensers were applied to series-wound motors they would be coupled in shunt to the field windings; but the objections above mentioned are equally applicable. A most important point to be noticed in connection with condensers used in this manner is the relatively high pressure which might occur at the field terminals owing to fluctuations in the current. This difficulty can be obviated by arranging the condenser and windings in sections, but such a plan is open to objection on the score of complication. Messrs. Hutin and Leblanc* have recently patented several modifications of designs involving condensers.

An interesting modification of the shunt-wound single-phase motor has been designed by Messrs. Stanley and Kelly. It is well recognised that the lag of the armature current does not coincide with that of the field current in an ordinary shunt-wound motor supplied with an alternating current, and hence the torque is not proportional to the armature current, but has a maximum for some particular value which must be determined experimentally for each machine. To meet this difficulty these gentlemen place a condenser in series with the shunt coils, and put short-circuited coils in recesses cut in the pole pieces. These coils carry currents induced by, and therefore proportional to, the armature current, but always in such a direction as to tend to decrease the self-induction of the armature coils, and consequently the lag of its current also. The arrangement has the disadvantage of raising the interpolar resistance, and is likely to cause serious distortion in the main field.

It has also been proposed to supply the idle currents prevailing with alternate-current working by suitable condensers placed across the supply mains, preferably at the transformers substations.

3.—*Split-Current Rotary Field Motors.*

Another attempt has been made in the direction of splitting the main current into two separate branches with phase differences of 90deg., and so producing a biphase rotary magnetic field, the armature circuit being closed on itself, or through an external resistance, and carrying a current induced by the revolving field. In principle this machine is similar to a Tesla motor supplied with two separate currents, one of them lagging 90deg. If a current be divided into two circuits with different coefficients of self-induction, the current in one will lag behind that in the other; and if the one circuit have no self-induction but capacity, and the other have relatively a large self-induction, then the phase difference can be made as near 90deg. as desired. Such a machine has been designed by Messrs. Hutin and Leblanc, but the author does not know how far it has been successful in practice. The points gained by this arrangement, however, mark a considerable advance in the design of alternate motors for use off ordinary supply mains. The motor is self-starting, non-synchronous, if stopped through overloading will start again as soon as the excess of load is removed, and is self-exciting. But it appears to be still far from perfect; for, owing to the armature reactions on the field, it is difficult to see how the current, in the circuit containing the condenser, can be self-adjusting for varying loads with a fixed pressure of supply; and consequently the output of such a motor will probably be less than that of a Tesla one with two independent currents. The difficulties attending the condenser are precisely the same as those previously referred to with the synchronous type of motor.

Messrs. Stanley and Kelly have recently devised a quadrature motor which presents some interesting features. In one of the circuits is placed a solenoid with low ohmic resistance but large self-induction; and in the other circuit is a series of secondary batteries which have capacity, and, therefore, act as a condenser. The result arrived at is a lag of 45deg. in the current of the inductive circuit, and a corresponding advance in the capacity branch, the result being a total difference of phase of about 90deg. between the two currents. The battery does not need to have large storage capacity; and as the number of plates is arranged so as just to prevent electrolysis there will be no "forming." But lead plates used in this manner in diluted sulphuric acid rapidly sulphate, and hence are likely to give trouble. Iron plates in caustic soda are also rapidly affected, and even carbon soon crumbles away. Platinum seems to be the only reliable material, and this at its present price is too costly.

4.—*Multiphase Alternate Motors.*

Professor Ferraris, in 1885, experimented with multiphase currents, and published his results in March, 1888, at Turin; and in May of the same year Tesla showed a rotary motor running with four wires; and Bradley, Haselwander, Wenstrom, Elihu Thomson, Dobrowolski, Brown, and others have introduced various modifications and improvements. The first practical demonstration was made by Dobrowolski and Brown with the Frankfort Lauffen plant.

It should be noticed that in all rotary-field motors and dynamos, it is not the current, but the resulting magnetism, that rotates; thus, if there are two circuits and four poles, the magnetism will be displaced 90deg. with each wave of current. In order to see this more fully, a simple case may be instanced. Fig. 1 is a four-pole diphase motor of elementary type, with a closed-circuit armature, having neither brushes nor commutator. There are two alternating exciting circuits, A A_1 and B B_1, in quadrature. Suppose that A and A_1 be magnetised so as to cause lines of force to pass from A to A_1 through the armature C. Then B and B_1 will be neutral, for there will be no current in them at this moment. Next, the current in A A_1 will gradually die away and that in B B_1 will steadily rise in an equal and opposite ratio, until the magnetic flux is from B to B_1, and A and A_1 are neutral. This cycle will be repeated, but with one alteration—the current in A A_1 will rise to a negative maximum (assuming it to have been positive before), and the flux will be in the direction of A_1 to A and in the next wave from B_1 to B. Carefully noting these changes, it is seen that the magnetic field has rotated once for a complete ∿ in each of the circuits; and therefore the speed of the

* Under the auspices of Messrs. Rothschild, who have generously voted the sum of 175,000 francs to enable them to carry out experiments with alternate motors on a commercial basis.

Hosted by Google

field rotation is N/n, where N is the number of $\sim$ per second, and n is the number of pairs of poles in one circuit. In the case referred to, since $n=1$, the revolutions of the magnetic field will be the same as the number of $\sim$. To make a diphase dynamo it is necessary to replace the closed-circuit armature by a suitable electro-magnet having as many free poles as there are poles in one of the alternate-current circuits, to excite this magnet with a continuous current, and to cause it to revolve.*

Then diphase periodic currents will be induced in the two circuits A A_1 and B B_1, the phase difference between them being 90deg. Mathematically the currents may be expressed thus:—That in A $A_1 = K \sin a$; that in B $B_1 = K \cos a = K \sin (a - \pi/2)$,

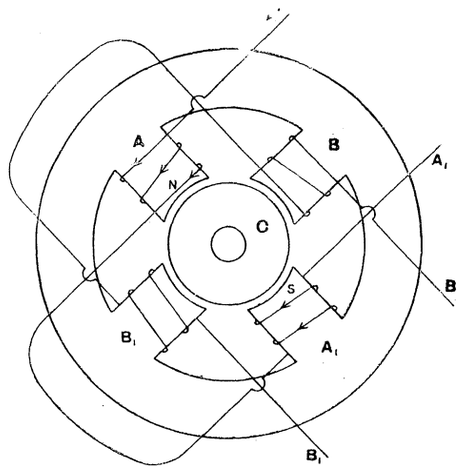

FIG. 1.—Four Pole Two-Phase Motor.

which shows the phase difference between the two currents. Now K is a constant for the particular machine, and a is a measure of the angular motion of the field. It will be seen that the current in A A_1 is a maximum when a is equal to $\pi/2$ and $3/2.\pi$, and is zero when a is equal to O and π; the converse of this is the case with the current in B B_1.

Diphase systems require either four wires—*i.e.*, two for each circuit—or else the cross-section of the common return must be increased by 1·4 times for the same loss. This is inconvenient on account of both cost and complexity; but a far greater objection for large plants seems to be the apparently excessive variation in the field excitation, yet this view is strongly combatted by many competent engineers. Let Fig. 2 be carefully examined. Curves A and B show the current-fluctuations in the two circuits, and D that in the common return.

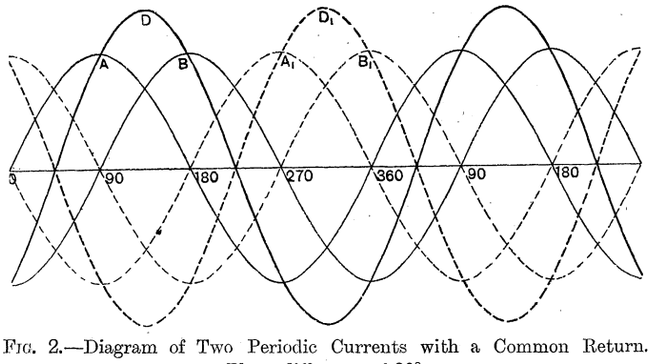

FIG. 2.—Diagram of Two Periodic Currents with a Common Return. Phase difference of 90°.

The magnetic field will be caused by A and B alone, and, therefore, will be proportional to their sum at any instant. When A is a maximum B is zero, and the induction at this moment is proportional to the current in A alone, and is equal to, say, $C \sin \frac{\pi}{2} = C$. When A and B are equal, as at 135deg. of field rotation, the induction is proportional to $2\,C \sin 135° = C\,1.4$. Thus the excitation varies between 1 and 1·4, the difference being nearly 30 per cent. of the highest value. The mean variation will be only about 15 per cent., it is true; but hysteresis and self-induction are proportional to the limiting values of the excitation, and eddy-currents approximately to the squares of these differences. Self-induction decreases the output for a given weight of material, and also by increasing the lag may largely augment the idle current for small loads.

To illustrate the fluctuation of the field excitation and consequent induction the sign of the negative curves in Fig. 2 may be changed, and they may be plotted above the time line as if they were positive in value; or two fresh complete curves may be drawn, as shown in dotted lines and marked A_1 and B_1 in Fig. 2, referring to the next two impulses of current immediately succeeding waves A and B. Both these diagrams are justified by the consideration that each circuit in the motor contains at least two coils wound in opposite directions, and thus produces poles of different signs; and, therefore, the magnetism rotates continuously.

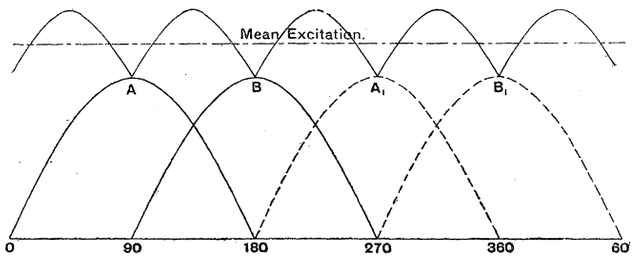

FIG. 3.—Diagram of Excitation Variation with Two-Phase Current. Phase difference of 90°.

In Fig. 3 the sign of the negative curves has been changed, and the excitation fluctuation is shown by the top curves, which may be regarded as having reference to one of the poles of the rotary field, say the North pole; while with the double arrangement shown in Fig. 2, since there are two sets of curves, one positive and the other negative, the variations of both poles are indicated. But as the fluctuations are sufficiently defined by the first method, the duplication involved in the latter seems to be unnecessary.

In the preceding considerations the armature reactions have been neglected. These are not easily estimated without some experimental acquaintance with the machine in question. But their effect will be a maximum at starting, and will decrease as the armature speed increases, and would be *nil* if the speed of armature and field coincided, *i.e.*, if the motor worked synchronously. The last condition is unattainable even with no load, for the friction of the bearings and air requires a certain amount of current in the armature to overcome it. Generally speaking, the armature reactions tend to weaken the resultant magnetic field, and also to lessen the torque for a given current.

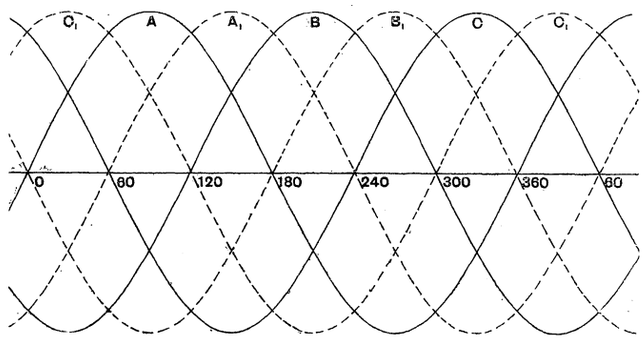

FIG. 4.—Three Periodic Currents separated by a Phase Difference of 120°.

5. *Triphase or Drehstrom Circuits.*

An inspection of Fig. 3 will show that in order to reduce the variation of the field magnetism it is presumably necessary to increase the number of circuits. Take four with phase differences of 45deg. The field excitation will be nearly constant, but eight wires will probably be required; for it is doubtful whether common returns similar to a direct-current five-wire system would be practicable. Yet the next advance in multiphase working was made by using three circuits with currents differing by 120deg. in phase.

* Rotary magnetic-field machines under certain conditions are reversible. See *Electrical Review*, February 10, 1893, in which an experiment is given showing the reversibility of a "three-phaser." Mr. Ernst Danielson, the experimenter and writer of the article, says that this depends on the fact "that when two single or multiphase machines are working synchronously, the current-phase is in advance of the pressure of the generator, while it lags behind that in the motor." In practice, however, up to the present, it has been found advisable to excite the field magnets of alternate dynamos with direct currents. In the future some means may be devised by which multiphase generators may be made self-exciting; yet it is questionable whether this is worth the trouble of any complication.

Hosted by Google

Since the phase difference is increased, this does not seem a self-evident improvement; but on closer study it is seen that the excitation is more constant, and that the algebraic sum of the three currents is equal to zero.

In Fig. 4 let A, B and C represent three periodic currents separated by a phase difference of 120deg.; and let the instantaneous values of the currents be severally represented by C_1, C_2, C_3. Thus,

$$C_1 = K \sin \alpha \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$C_2 = K \sin \left(\alpha - \frac{2}{3}\pi \right) \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$C_3 = K \sin \left(\alpha - \frac{4}{3}\pi \right) \quad . \quad . \quad . \quad . \quad . \quad (3)$$

And $C_1 + C_2 + C_3 = 0$ by hypothesis. For

$$K \left\{ \sin \alpha + \sin \left(\alpha - \frac{2}{3}\pi \right) + \sin \left(\alpha - \frac{4}{3}\pi \right) \right\} = 0,$$

which is easily proved to be the case.

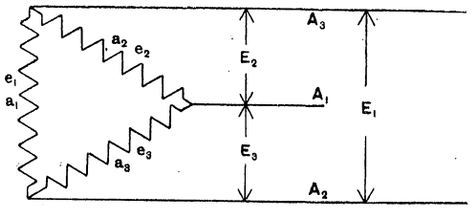

FIG. 5.—*Parallel*, or *Closed Circuit*, or *Triangle* Drehstrom Coupling.

Drehstrom working is accomplished by parallel or series coupling of the circuits, the two methods being severally known as the *star* and *triangle* systems. The author regards as the field magnet that part of the machine in which the rotary field is produced. In a triphase motor, then, the field magnet will be that part which receives the Drehstrom from the mains, regardless of whether it rotates or not. In the dynamo there can be no confusion, for the field magnets, in present designs at any rate, always rotate and are excited by a separate direct current. In this Paper large capitals are used to distinguish the mains carrying the Drehstrom, and italics to denote the three windings on the field-magnets of the motor or the armature of the dynamo.

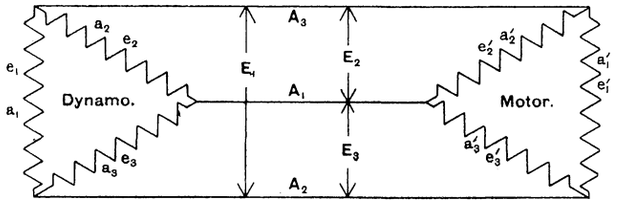

FIG. 6.—Drehstrom Dynamo coupled to a Motor.

Suffixes are used to mark the phase order of the circuits. It is also assumed that the effective values of the current are read by dynamometers, and that of pressure by voltmeters of the hot-wire or electrostatic type.

The *parallel* or *closed circuit*, or *triangle* coupling, is shown in Fig. 5. Let A_1, A_2, A_3 be the effective values of the several currents flowing in the mains, and a_1, a_2, a_3, the corresponding effective currents in the coils. Also, let E_1, E_2, E_3 be the effective pressures at the terminals of a_1, a_2, a_3. And assume $A_1 = A_2 = A_3$; then $a_1 = a_2 = a_3$, and $E_1 = E_2 = E_3$. And let there be no self-induction or capacity.

With these assumptions, since a is in phase with e, and A lies 30deg. removed from a, it follows, if the mains be fed with

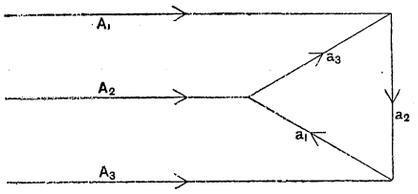

FIG. 6A.

a combined three-phase current, (as in Fig. 6), that the current in one main will differ in phase by 30deg. from the pressure between it and the two other mains. This is seen to be the case from the geometrical relationship of the coils and the mains. And it can also be proved that the effective value of the current in each of the mains is equal to 1·732 times the effective current in each of the coils, when the circuits are equally loaded. In Fig. 6A let the currents in the mains and in the coils be considered positive when flowing in the direction indicated by the arrows, and let the phase and magnitude relations of these currents be represented by Fig. 6B. Then if the diagram 6B be supposed to revolve uniformly around its centre, the length of the projections of the sides of the diagram on any straight line will represent the instantaneous values of the corresponding currents, for it is plain that these projections satisfy all the necessary conditions, viz.:—

$$\left.\begin{array}{l} A_1 = a_2 - a_3 \ldots\ldots \\ A_2 = a_3 - a_1 \ldots\ldots \\ A_3 = a_1 - a_2 \ldots\ldots \\ A_1 + A_2 + A_3 = 0 \\ a_1 + a_2 + a_3 = o \end{array}\right\} \text{All instantaneous values—}i.e.\text{, the lengths of the projections of the corresponding sides of Fig. 6B.}$$

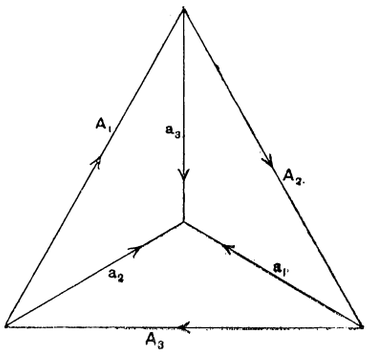

FIG. 6B.

Again, the sides of the diagram 6B are proportional to the effective values of the corresponding currents; and if the load be equally distributed between the three mains, then for effective values, $A_1 + A_2 + A_3 = 0$; and $a_1 + a_2 + a_3 = o$; and $A_1 = 2a_2 \sin 60°$; or, generally, $A = 1{\cdot}732\, a$.

The above demonstration was suggested by Dr. Sumpner.

By a similar diagram the relation between the effective pressures on the coils and mains in the *open* or *star* arrangement can be shown to be $E = 1{\cdot}732\, e$. See (*b*) of this section.

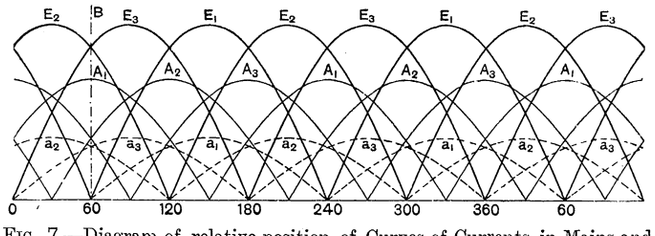

FIG. 7.—Diagram of relative position of Curves of Currents in Mains and Coils of a Closed-type combined Drehstrom Circuit with no Self induction or Capacity.

The relative position of the phases of currents and pressure in the mains and coils of a combined Drehstrom circuit of the closed type with no self-induction are shown in Fig. 7 (E and *e* have the same value, and coincide in phase). It will be seen that the maxima of the currents in the mains, A, are always midway between those of the coils, *a*, and that the phase difference between them is 30deg.

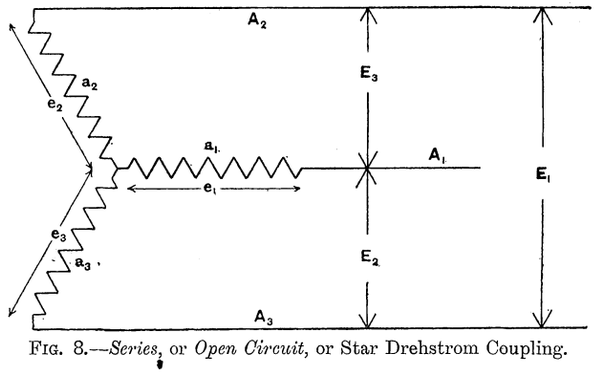

FIG. 8.—*Series*, or *Open Circuit*, or Star Drehstrom Coupling.

(*b*). The *series*, *open circuit*, or *star* coupling is shown in Fig. 8. As before, let there be no self-induction or capacity, and let $A_1 = A_2 = A_3$; $a_1 = a_2 = a_3$; and $E_1 = E_2 = E_3$. Now, since the mains A are in series with the coils *a*, and there is by hypothesis no self-induction or capacity, $A_1 = a_1$, $A_2 = a_2$, and $A_3 = a_3$. But the pressures between the mains are not the same as those at the coil terminals. And *e* will lag 30deg. behind E and will be numerically equal to E/1·732, or $e = E/2 \sin 60°$, and therefore $E = 1{\cdot}732\, e$.

Hosted by Google

The phases of current and pressure in a combined Drehstrom circuit of the open type are shown in Fig. 9 (A and a have the same value, and coincide in phase).

The conclusions thus arrived at are true only on the assumptions (a) that the coils themselves have no self-induction, and (b) that both the coils and the mains are equally loaded. The first condition is never found in practice, and the second is only likely to obtain with small motors, and then only in an approximate degree. The effect of self-induction is to cause the current in the coils to lag behind the pressure at the terminals. To measure exactly the power in a Drehstrom system, then, is a complicated task ; but it can always be done by measuring the work performed in each of the separate circuits and adding the quantities.

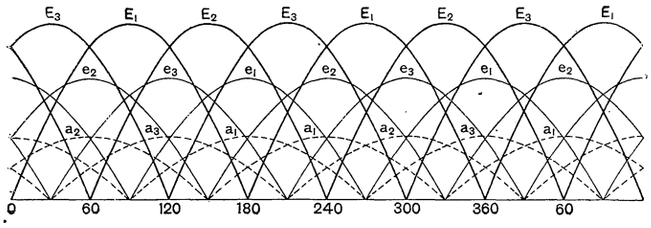

FIG. 9.—Diagram of relative Position of Curves of Pressures and Currents in the Coils and Mains of the *Open-type* combined Drehstrom Circuit with no Self-induction or Capacity.

In Fig. 5 the energy $=3\ a\ e=3$ E.A/1·732 $=$ E A 1·732 if the three circuits be equally loaded, and there be no self-induction or capacity. In Fig. 8, also, the energy $=3$ A $e=3$ A.E/1 732 $=$ E A 1·732 on the same assumptions.

So it appears, if there be no self-induction and an equal load in each circuit, that the number of amperes in one of the mains multiplied into the pressure between two mains into 1·732 gives the power in watts. If there be self-induction, the above quantity must be multiplied by the cosine of the angle of lag between the

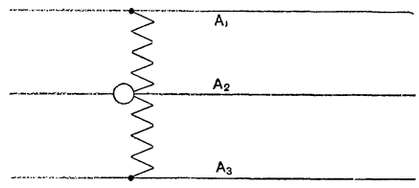

FIG. 9A

current and the pressure. The energy absorbed by a motor, therefore, will be expressed by E A 1·732 cos ϕ, where ϕ is the angle of lag. If the three circuits be equally loaded, the power can be measured by one wattmeter (*see* Fig. 9A). Put the current coil in one of the mains, say A_2, and take two readings, one with the pressure coil coupled between A_1 and A_2, and one with it coupled between A_2 and A_3. The power will be equal to the sum of the two readings. And if the load be unequally distributed, two wattmeters are required (*see* Fig. 9B). Place the current coils in two of the

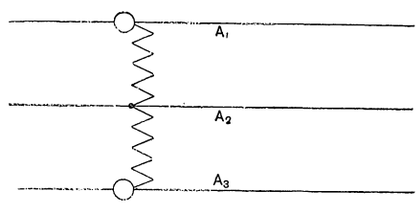

FIG. 9B.

mains, say A_1 and A_3, and couple one pressure coil between A_1 and A_2, and the other between A_2 and A_3. The power is then the sum of the two wattmeter readings.

The author is indebted to Dr. Sumpner for the above methods of measuring the power in multiphase circuits by wattmeters. They are also applicable for reading power with direct currents.

In part (a) of this section it was shown that with combined three-phase currents, even when neglecting the self-induction of the coils, there is a constant phase difference between the current and the line pressure. This, although not in itself a direct loss, is the cause of great difficulty in measuring, regulating, and controlling the currents, and also reduces the output for a given weight of material. Hence it has been found expedient to work the dynamo circuits unconnected and to use six or more separate coils. The currents from these are combined by a suitable transformer so as to convert the secondary currents into a combined high-tension rotary current with phase differences of 120deg. This high-pressure current is reduced at the motor end of the line by another suitable transformer and subdivided as required. In the transformers, says Mr. Dobrowolski, there is not the same constant difference of phase of 30deg. (between the current and the pressure) ; but, owing to the connections of the secondary coils, the transformation ratio is not equal to that between the primary and secondary turns ; so the latter must be increased to the extent of this difference. The ratio is 2 : 1·732, or a difference of 14 per cent., neglecting all losses from other causes than the connections. The efficiency of Drehstrom transformers is probably not quite so high as that of single-phase ones, but it is not much less ; and when the advantages of low-pressure dynamos and motors with high-pressure transformers is fully appreciated, the slight difference in efficiency appears insignificant.

The next point for consideration is the pulsation of the magnetism in the rotary field. This is not a simple matter to represent in a graphic manner, for the magnetic field is not merely the result of the *inducing* currents in the Drehstrom coils, but it is also largely affected by the frequency and magnitude of the *induced* currents in the closed coils of the armature, which vary from instant to instant with every fluctuation of load. The frequency of the induced currents will always be less than that of the exciting current—attaining its highest value at full load when the slip of the armature is greatest. It is expressed by $(N-n)/60$, where N $=$the number of revolutions of the magnetic field per minute, and $n=$that of the armature. (If $N=2{,}400$ and $n=1{,}920$, then the frequency will be 8 per second.) The average pressure acting in the closed coils will be given by the expression K C F $a\,10^{-8}$, where K $=$a constant, C $=$the number of turns counted all round the

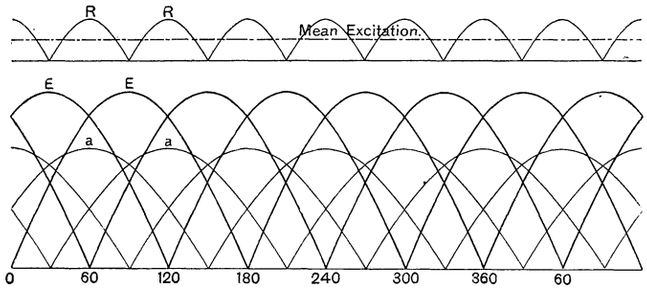

FIG. 10.—Diagram of the Excitation Fluctuations in a combined Closed-type Drehstrom Circuit.

periphery of armature, F $=$the average number of lines of force from one pair of poles, and $a=$the number of alternations per second of the armature induced currents. In determining the excitation for multiphase motors and dynamos, it is therefore necessary to make two calculations, one for full and one for light load, just as with direct-current machines.

It is clear that it is not possible to represent the changes of the rotary field magnetism by a general diagram. Fig. 10 shows diagrammatically the relative position of the current and pressure curves in a combined Drehstrom circuit, with the resultant excitation, assuming the armature reactions to have no effect—*i.e.*, the field and armature are supposed to rotate at nearly the same speed. An arbitrary angle of lag of 30deg. between the pressure and the current in the exciting coils has been assumed, and the curves have been drawn to suit the sine law. The pressure is shown in E_1, E_2 E_3, and the current in a_1, a_2, a_3. The resultant excitation is indicated in curves R, R, R, the limits of which are 2 a and 1·732 a, a mean difference of about 7 per cent. If the magnetism varied as the excitation, then the same fluctuation would occur in the rotary field, but, owing to hysteresis and eddy-currents, the mean variation is probably not much more than half as great, say from 4 to 5 per cent.

Now the torque will vary with the ampere turns, the frequency of the current, and the number of lines of force in the armature; or, the torque $=$C i_a F a/K_1, where i_a $=$ the armature current, and $K_1=$a constant, and the other symbols have the same signification as above. The magnetism is determined by the field excitation, and the number of turns of wire is of course fixed for a given armature ; hence, to increase the torque, it is necessary that the armature rotate more slowly.

This "slip" increases both the frequency and the magnitude of the armature current, thereby weakening the resultant field and lowering the counter E.M.F. of the field-magnet coils, and allowing more current to flow in the exciting circuit. But since the total magnetism decreases as the armature current increases, there is a point at which the torque is a maximum.

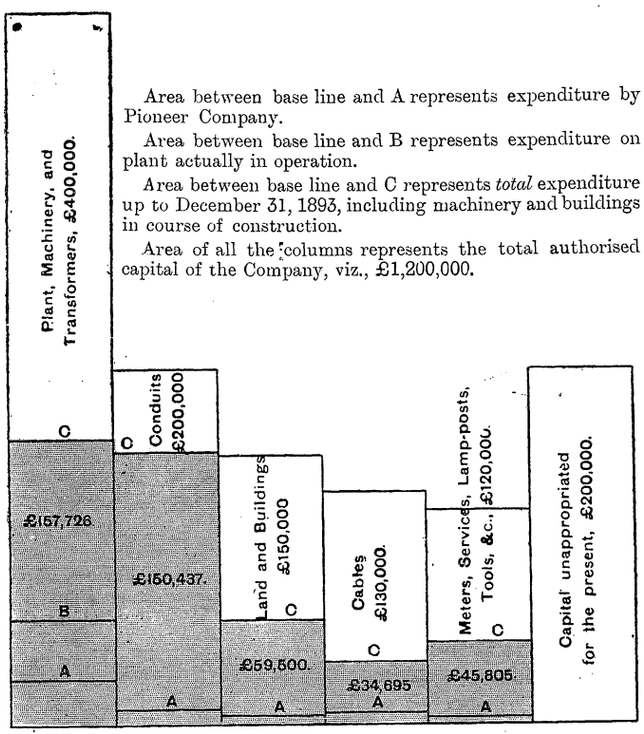
Hosted by Google

This corresponds to a definite current,* which is not the starting or maximum current, and hence these motors do not exert their greatest effort at starting. In order to avoid large rushes of current when closing the exciting circuit, it is advisable to insert variable resistances in series with the armature windings. This is specially necessary with large machines, and it appears probable from this reason, as well as from other considerations, that large Drehstrom motors will always be designed with stationary armatures and revolving field magnets.

(To be continued.)

THE CITY OF LONDON ELECTRIC LIGHTING COMPANY.

The City of London Company has continued this year the excellent custom of bringing home leading facts to its shareholders by the aid of curves, and we publish this week the most interesting of a set of three diagrams presented to the shareholders at the annual meeting last week.



Sir David Salomons remarked that such graphic representations told more than "the most elaborate and eloquent speech, or the most carefully audited accounts." We sincerely hope that they do; for we have known many an elaborate discourse to assembled shareholders which told nothing, and have not infrequently seen rigidly-audited balance-sheets which, owing to the omission of a negative sign in front of certain items, told something less than nothing.

The main fact, brought out (in vivid pink, or shall we say "*couleur de rose*") on the original diagram, is that the City of London Company has been wise in time, and by a lavish, but thoroughly judicious, expenditure on conduits, has carried out its underground work economically—by having done it all at once—and minimised, as far as is humanly possible, the bitter cry of the city man by administering one large dose of discomfort in lieu of several small ones.

* It is clear that the particular current for maximum torque is dependent mainly on the magnitude of the armature reactions, and if the latter were sufficiently small, the greatest torque might be obtained at starting, as is the case with a series-wound direct-current machine. With commutatorless Drehstrom motors it is probable, in the author's judgment, that the maximum effort will be obtained with a current little greater than that required for the greatest output.

BOARD OF TRADE REGULATIONS WITH REGARD TO SAFETY DEVICES FOR ALTERNATE-CURRENT SUPPLY.

We have received the following document from the Board of Trade for publication :—

Whereas in certain regulations made by the Board of Trade under the Electric Lighting Acts and certain Provisional Orders and licences granted under those Acts, it is provided that where the supply of energy is transformed at a converting station, some means or apparatus approved by the Board of Trade shall be provided which shall render it impossible that the low-pressure distributing mains shall be at any time charged to a dangerous difference of potential from the earth, owing to any accidental contact with, or leakage from, the high-pressure system either within or without the converting station ;

And whereas under such regulations it is also provided that where any transforming apparatus is installed on a consumer's premises some means or apparatus approved by the Board of Trade shall be provided which shall render it impossible that the low-pressure service lines and consumer's wires shall be at any time charged to a dangerous difference of potential from the earth owing to any accidental contact with, or leakage from, the high-pressure system either within or without the transformer ;

Now, therefore, the Board of Trade approve of the following arrangement for use in any case where a high-pressure supply of energy is converted to a low-pressure supply by alternating-current transforming apparatus, as a means of preventing contact between the high and low-pressure conductors within such transforming apparatus, viz. :—An arrangement such that by the construction and winding of the apparatus any wire or other conductor forming part of the low-pressure supply circuit within the transforming apparatus is separated from any wire or other conductor forming part of the high-pressure supply circuit within the transforming apparatus in every part by a wire or other conductor possessing sufficient sectional area, which is efficiently connected to earth, but is not in metallic connection with either the high-pressure or low-pressure supply circuits.

Signed by Order of the Board of Trade this 22nd day of March, 1893.

(Signed) COURTENAY BOYLE,
Acting Secretary, Board of Trade.

EARTH-CURRENTS IN INDIA.*

BY E. O. WALKER.

Papers on this subject were published in the *Journal* for the years 1883, 1884, 1888, and 1891. More recent observations, in connection with those previously taken, have led to an identity being revealed between the variations of these currents and those of atmospheric pressure. It is thought to be of interest, as the comparison is novel, to give a brief account of the facts which seem to establish this identity. In doing so references must necessarily be made to the former Papers. In the study of this subject much assistance has been afforded by the records kindly placed at my disposal by Mr. C. Chambers, F.R.S., Superintendent, Colaba Observatory ; Mr. Michie Smith, F.R.S., Government Astronomer, Madras ; and Mr. E. Kitto, F.R.Met.S., Superintendent, Falmouth Observatory ; and by information furnished by Mr. W. Ellis, F.R.A.S., Greenwich Observatory ; reference has also been made to the Bombay Meteorological Observations of 1845, and to the *Encyclopædia Britannica* (9th Edition, Vol. XVI. — "Meteorology").

The observations in India were not as a rule taken with a sensitive galvanometer, for the currents were of sufficient magnitude in the localities in which observed not to require it. The use of a sensitive galvanometer involves complications from weak electro-chemical and thermal currents produced at junctions, and the magnetic system is subject to displacement from terrestrial magnetism, the effects of which are difficult to screen. In all delicately-suspended magnets with long indicators, or with reflectors and distant scales, these effects are considerable.

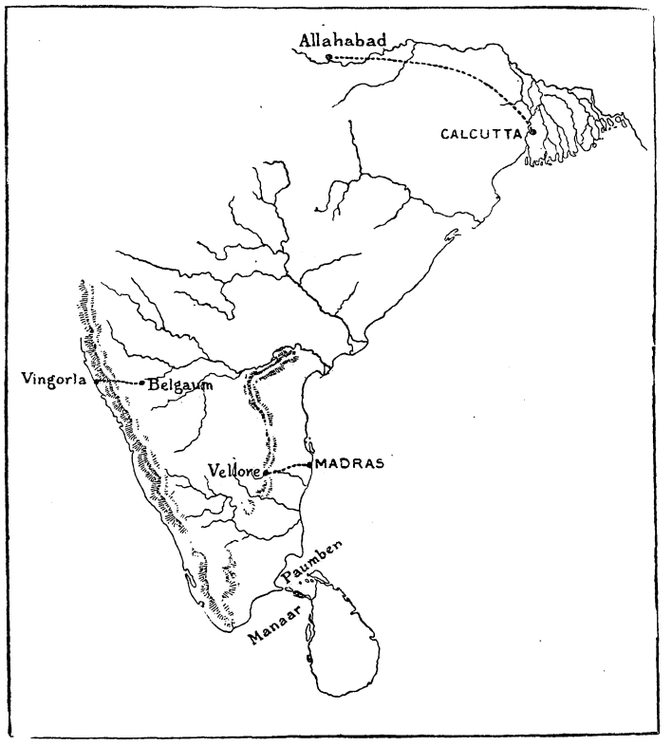
It is necessary to remark that the long periods of settled weather in India are favourable to the regular recurrence of the same variations in meteorological phenomena from day to day during those periods ; and this has been found to be the case with the earth-currents. For fully 30deg. north and south of the equator the lines of maxima and minima run north and south, but in higher latitudes these directions are changed. Again, the amplitude of the oscillations of atmospheric pressure is greater in equatorial than in higher regions, and so far as can be ascertained, the earth-currents have higher electromotive forces in the former than in the latter. On the whole, therefore, India offers a better field for observation than the British Isles, where the weather is subject to such large and frequent disturbances from often unknown and unforeseen causes.

* Paper read before the Institution of Electrical Engineers, March 23rd.

Hosted by Google

In my Papers of 1884 and 1888 reference has been made to difference in elevation between two places being favourable to the production of an earth-current, and to the probability that at any time difference in atmospheric density is also effectual in this way. Condensation and dispersion of aqueous vapour at high elevations have by other observers been shown to affect the direction of the current. On the coast of India the disturbances to telephonic communication, when earth has been used, have been very great on long circuits during that part of the day when solar heat was most active and when the sea-breeze prevailed, the cause apparently being, that electrically-charged films and particles of vapour were driven across the wires and discharged into them. The effect was to produce a hissing or grating noise on the telephone which often drowned the voice of the operator. It is thought, then, that these considerations, coupled with the results of fresh observations which follow, may lend colour to the supposition that the movements of aqueous vapour, as evinced by the daily barometric oscillations, are active in the production of earth-currents.

Observations of earth-currents have been taken on some days in March and April, 1891, between Belgaum and Vingorla; in February and July, 1892, between Madras and Vellore; in June and July between Paumben and Manaar; those of September and October, 1887, between Calcutta and Allahabad, also illustrate the same features of the daily recurrent phenomena. It is found that almost always the current flows in the morning from the inland places of observation to those on the sea-coast. A sketch map is



appended to show the geographical positions of the places indicated, In the afternoon the direction of the current is reversed. On the sections of lines from Belgaum to Vingorla and Madras to Vellore, currents of high electromotive force are observed from a halfo five volts they are remarkably steady, and cannot be producedby electr-o chemical or thermal influences at the earth-plates. Some observations kindly taken on one of the Madras-Penang cables in July, 1892, by Mr. Wolfe, acting-superintendent at Madras of the Eastern Extension Telegraph Company, also showed that electromotive forces of from 0·1 to 14·4 volts were operating from 6:37 a m. to 9:11 a.m. (between which hours observations only were made), and go to strengthen the conclusion that comparatively high forces do prevail about the time of the morning maximum of atmospheric pressure. The curve which shows the changes from early morning to evening was given in Plate I. of my Paper of September, 1884, and this is reproduced here (Diagram II.). These diurnal phenomena are occasionally reversed in times of cyclonic storms. The cables from Madras to Penang give evidence of similar effects.

The observations taken at Paumben on the line to Manaar are very instructive; they comprised seven days, the current was very weak, and exhibited no regularity in ebb and flow. The line is about 50 miles in length with a cable in circuit, and runs east and west. The difference between the phenomena exhibited here and those of Vellore and Belgaum I attribute to the fact that there can be but little difference in the meteorological conditions of Paumben and Manaar, and barometrical oscillations of the same sign and amplitude occur synchronously at the two places. It is to be regretted that this supposition cannot be confirmed by records. It should not be omitted, however, to note that Paumben is only thirteen miles south of the magnetic equator, and it is possible that magnetic forces there are variable to a greater extent than at the other places noted above. The photographic records of the earth-current at Greenwich Observatory in the line running east and west, prior to the disturbance which is caused by the City and South London Railway currents, show a rise and fall in the earth-current similar to that exhibited in Diagram II. herewith, although in a circuit only three miles in length the electromotive force is very small.

The barometric curves in Europe and in India as regards the diurnal oscillations are similar in respect of the morning maximum and afternoon minimum. Opportunity has been taken to verify

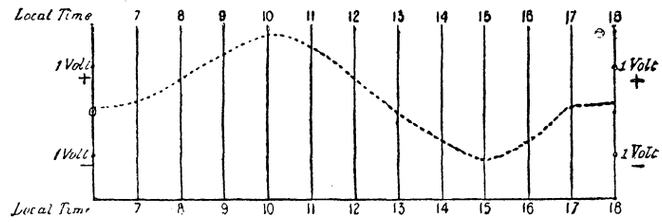


Diagram I.

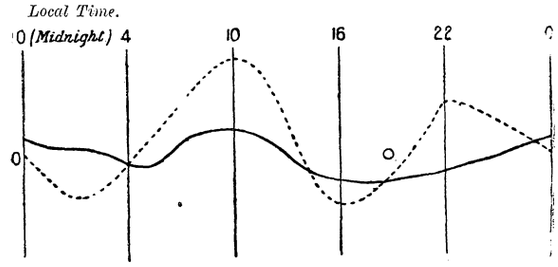
this assertion by comparison of the Bombay curve with that of Falmouth. The general characteristic of the latter is naturally much obscured by the fitful weather to which this locality is subject. But on still days this similarity is undoubted. The morning maximum occurs from 9 a.m. to 10 a.m., occasionally as late as 11 a.m., and the afternoon minimum from 3 p.m. to 5 p.m. In Bombay, on three days in July taken at random, maxima occurred at 10 a.m., at 8 a.m., and at 11 a m., and the minima on the same days at 5 p.m., 4 p.m., and 3 p.m. This variability in times of maxima and minima also characterises the earth-currents. The curve for Vienna, as given in the *Encyclopædia Britannica*, is shown with that for Bombay in Diagram II., the two being typical to a large extent of the diurnal barometric oscillations in temperate and in tropical regions. Could comparisons be instituted between the electromotive forces of the earth-currents in those two regions, it is not unlikely that the typical curves would be similar to these. In India, at least, a large number of observations warrant the belief that the barometric curve is also



Curve at Bombay ·····
" " *Vienna* ——

Diagram II.

correspondent to that of the earth-current in its rises and falls and change of direction. Experience at present only permits me to speak of the morning and afternoon changes. It has not been possible in most localities here treated of to secure observations during the night.

Diagram III. shows the mean daily variation in declination in Madras for the month of July, 1855. Tables for later years are not available. But independent observations recently made show that the variation at present is very similar. It is preferable to give the curve constructed from the Madras Observatory tables, which contain the indications of exact instruments. The declination curve for the 6th July last, furnished to me from the Colaba Observatory, Bombay, bears the same character. It would seem, on the whole, that the earth-current tends to maxima when the diurnal variations in declination are at their minima. If this be a fact it is one of great interest, but it cannot be accepted without more prolonged observations in different localities.

Hosted by Google

The earth-current curve is by no means a smooth one, and the rate of oscillation is a factor which is of great importance in forming a correct conclusion as to the origin of the current. The time of change of the needle of the galvanometer through several degrees, while on the move on quiet days, has therefore been observed. The motion on such days is slow, and shows on the occasions in question rates of change of force in four observations of 5·7, 9·0, 13·5, and 17·1 feet per hour only. In some similar observations made in Calcutta in 1887, a mean rate of only 0·5 foot per hour was ascertained. Be the cause of the current what it may, it may safely be asserted that it operates slowly on quiet days. This feature of the phenomenon is well worthy of further study.

It will not be going too far it is thought, in the light of the above facts, to surmise that the alteration in inductive capacity of the atmosphere by the action of solar heat occasions a slow redistribution of static charge upon the earth's surface, the aqueous vapour being the agent in this gradually progressive change. The uprisal of vapour under the influence of the sun in the early hours of the morning, and the condensation and fall in the afternoon, are in the East, and often in Europe, the phenomena of each day, and influence the barometric curves. If, as observation seems to show, high potentials are met with in the upper regions, these ascending and descending columns of vapour must be very potent in bringing successive portions of the earth's surface within their influence. So far as can be seen in India, the tendency in the morning is apparently to an inflow of negative electricity from sea-coasts to places inland where the barometric oscillations are large, and in the afternoon to an outflow. Thus, if there be induction from high regions, the gradual ascent of vapour in the air through heat promotes it, but the re-condensation later in the day of vapour operates to reduce it.

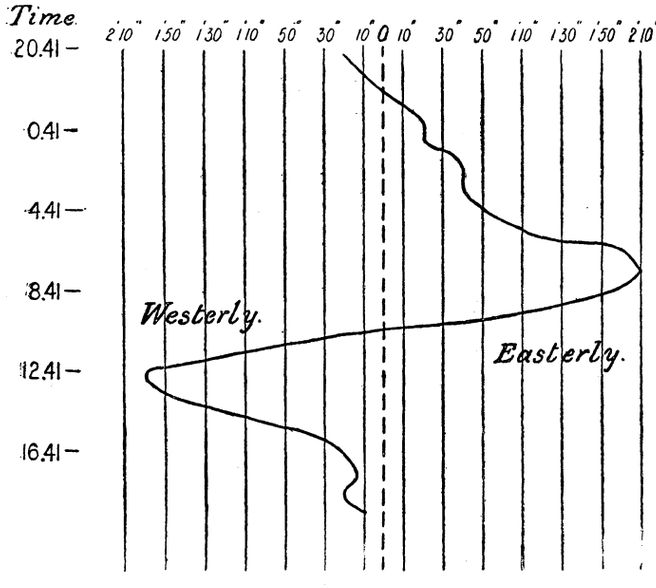


Diagram III.

It is felt that, in venturing upon this hypothesis, the cause of perturbations cannot be entirely satisfactorily dealt with. These are often so rapid in their changes that they fail to be registered in our observatories by photography, and are often far stronger than any forces measured on quiet days. During such disturbances the barometric trace scarcely varies from an even line, though in some cases minute oscillations of the mercury can be detected. It will be probably necessary to look for the cause of these violent changes to increased solar activity, evidences of which are, in fact, often seen at such times. If electrification in hige regions be due directly to the sun, the surface of the earth must partake of modifications of that condition.

DISCUSSION.

*Mr. ADAMS said he should like to have had a copy of the Paper earlier in order that he might have studied its various points. It really seemed to him that the author, if his ideas with regard to the effect of vapour were correct, had been dealing with local disturbances. There was, however, this fact which he thought would be admitted by all who had studied the question, that variations of the earth current, like variations of the magnetic elements in any one place, found their counterpart in degree, and in proportion to the local time, lunar and solar, in every other part of the earth. If the variations that were mentioned in the Paper were the ordinary variations, then they partook of a variation which occurred throughout the whole world. Now, if the Greenwich barometric results were studied, it would be found very largely that the weight of the atmosphere did appear to vary, and to coincide with the diurnal inequality, although there were many other variations underlying it. But in dealing with earth currents, as with magnetic variations, they must remember, and he thought it had been proved over and over again by different people, that they were dealing with parts of a grand whole, and not with local variations or variations due to local causes. He had never yet found anything in the shape of clear proof that an earth current or a magnetic variation had been due to any local cause. He knew it had been said that a snowstorm had come on and produced this, and that a change of wind had brought about that variation, but he could find no proof for anything of the kind. Now although he could not discuss the Paper as he would wish to do for want of the figures, he would nevertheless remark that, as in 1883 he pointed out that the earth-current variation took a tidal form, so now, after many more years of investigation, he would repeat that statement. With regard to the coincidence between the variation of the atmospheric weight and the earth-current variation pointed out in the Paper, it was to his mind a further evidence that the current variation and the magnetic variations were the results of variation in gravitation. Gravitation was without doubt varied by sun and moon, and, broadly, as a result we got corresponding changes in the earth's magnetic and electric conditions. Although he might be standing alone as to that view, he believed that a few years would show its truth. He was particularly interested in the results before the meeting, but he did not think they could be due to vapour change or to local effect of that kind, but must be looked at as part and parcel of great general variations which occurred in degree and proper sequence as to solar and lunar time at every other part of the earth.

Sir DAVID SALOMONS drew Mr. Walker's attention to Lord Kelvin's address to the Royal Society on the influence of the sun on magnetic currents on the earth.

*Mr. WALKER, in reply, said that a few years ago, on sending his earth-current curve to the Kolaba Observatory at Bombay for comparison with the magnetic curve of the day Mr. Chambers, who was in charge of the Observatory at Kolaba, noted a distinct similarity between the changes of the earth current, and that of the temperature of the surface soil in Bombay. It did not occur to him that there was anything more to be said on that subject just now; the observations in India were necessarily very limited, as they had few lines at their command which could be used for observation without detriment to traffic.

*The PRESIDENT (Mr. W. H. Preece) proposed a vote of thanks to Mr. Walker. The subject was one to which he had himself devoted a deal of attention, and on which he had written several Papers, and he had been intensely interested in the remarks Mr. Walker had made. But he would point out to that gentleman that he did not think he had in any way indicated that any direct distinction had been shown between currents due to atmospheric causes, and currents due to changes in the potential of the earth. Some thirty or forty years ago there was an extremely able Paper on this subject, giving the results of some observations made in America. In that particular paper it was shown unmistakably that it was necessary to draw a great distinction between earth currents and atmospheric currents, and by very ingenious contrivances it was shown that the currents due to atmospheric electricity were just as frequent as those due to changes in the potential of the earth. Mr. Walker did let out one thing which had great interest. It was a suggestion that the specific inductive capacity of the air might change. They were always taught and they were always accustomed to regard the specific inductive capacity of the air as one of Nature's constants. It had been given a particular value. It was generally supposed to have the value of 1, but they did not know what the value really was; indeed, they had not the least idea of what it ought to be, but at any rate, for purposes of calculation and for mathematical reasoning, it had been allotted the value of 1. Now, long experience in telegraphy had led him to believe that that was not true—that the specific capacity of air was not 1, and that the specific capacity of air was variable. He had tried innumerable experiments in endeavouring to prove that the presence of aqueous vapour in the air did change its specific capacity—but without success. There was this very striking fact, that in all instances in which he had compared the capacity of wires in England with the capacity of those in other countries, the capacity in England was invariably greater than in other countries. That might be due to the fact that our atmosphere was more charged with humidity than the atmosphere certainly was in America. It had been attributed, and he had attributed it himself, to the existence of earth wires on our poles, but although that might be some cause, the probability was that a change in the value of the specific inductive capacity would account for the difference. Another valuable feature in Mr. Walker's Paper was that he had given the value of these current in volts. He had tried often, through the columns of *The Electrician*, to call attention to the fact that observations made on earth currents in different parts of the world were absolutely valueless, because they did not give those very electrical measurements which enabled them to draw comparisons. They wanted to know the voltage, they wanted to know the direction of the lines observed, and they wanted to know their resistance. If they had the geographical position of the lines, if they had the measure of the voltage and the resistance of the circuits, they could from those facts deduce what electrical elements they desired. Mr. Walker had to some extent supplied that want, and he had given it in very clear language.

Royal Society.—The following Papers were down for reading yesterday before the Royal Society:—Dr. Hopkinson, F.R.S., E. Wilson, and F. Lydall, "Magnetic Viscosity;" F. W. Dyson, 'The Potential of an Anchor Ring."

"ZENITH" PORTABLE ELECTRIC LAMPS AND BATTERIES.

In our issue of February 17th we described and illustrated the application of the Bristol lamps and batteries to the lighting of omnibuses and other vehicles. Further developments in omnibus, bicycle, and railway lighting have now taken place, and the near future will doubtless witness the introduction of electric lamps into all our public conveyances. We illustrate in Fig. 1 the "Zenith" pocket lamp and battery; in Fig. 2 the Inspector's button-hole lamp; in Fig. 3 the fireman's portable safety lamp; and in Fig. 4 the interior of an omnibus in which a triple set of

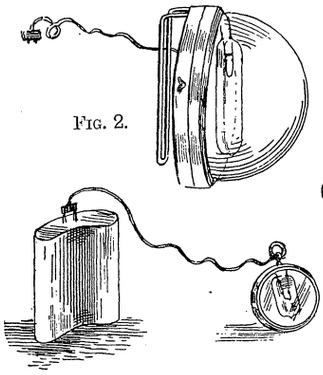

Fig. 2.

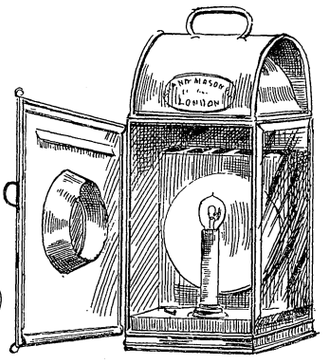

Fig. 1. Fig. 3.

"Zenith" accumulators and lamps, specially designed and constructed for omnibus lighting, are shown. The battery and lamp patents are owned by the "Zenith" Electric Light Company, of Kennington Park, S.E. The patentees claim that the "Zenith" battery plates, owing to their particular formation and the small amount of metal used in forming the frames, enables the use of a greater surface of active element than has hitherto been attained, and, consequently, a maximum of voltage with a minimum of cell capacity and weight.

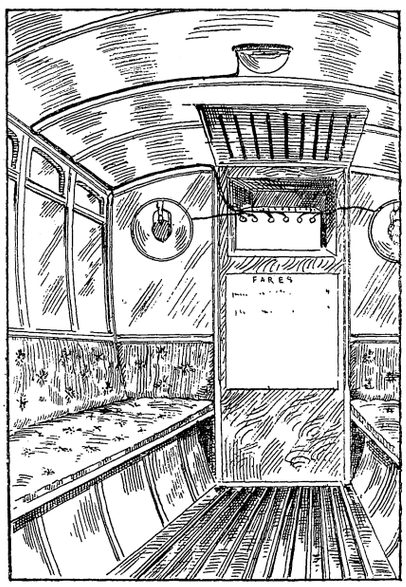

Fig. 4.

The positive plate frame is rectangular in plan, the internal edges being bevelled to form a key for holding the element, and upon the inner surface are two or more pointed projections pointing towards the centre, upon which are formed bevels corresponding to the bevel upon the frame, and for the same purpose. The negative plate frames are similarly formed, but without projections, in lieu of which are attached thin rods or wires of lead or lead alloy, preferably circular in cross section and occupying such a position that their ends impinge upon the bevel of the frame. These rods or wires may be either straight and extend from end to end, or crinkled, or both, or may be placed diagonally, or crossed. Suitable lugs are provided upon one of the smaller ends to facilitate coupling up. Both plates are filled in with paste composed of carbonate of ammonia and protoxide of lead or litharge, rendered plastic by the addition of dilute sulphuric acid, and this paste is smoothed off level with the frames and allowed to set, and then coated upon each side with a paste of peroxide of lead and water.

Fig. 1 is a portable pocket lamp and battery, the latter weighing, in the newest form, about 12oz., and the lamp is fitted in an imitation watch-case suitable for the waistcoat pocket. The patentees inform us they are arranging with W. H. Smith and Sons to have the battery and lamp on sale at their bookstalls throughout the country. The purchaser will buy the lamp and battery outright, and will afterwards be able to exchange an exhausted battery at any bookstall for a small sum. The battery is stated to last ten working hours, and the lamp gives a 1-c.p. light. These small lamps are also made with coloured glasses for photographic uses.

Fig. 2 is a button-hole lamp for use by omnibus, tramway, and railway ticket-inspectors. It is fitted with a small screw switch, simple in construction and effective. Fig. 3 is a fireman's lantern of the ordinary form, for use when the fireman is engaged in seeking for the gas meter to prevent an explosion. A 12-volt accumulator is fitted on a square block, and has a suitable switch and lamp attachment. The whole can be put inside the lantern and a safety-lamp be thus obtained, fitted with a reflector and showing a good light unaffected by wind or weather. Messrs. Shand and Mason are, we understand, supplying these lanterns.

Fig. 4 is an omnibus interior, showing the battery under the driver's seat. This is easily renewed from the inside. One box supplies the three lamps, and if a lesser number are required a third or two-thirds of the cells can be switched out. The triple set of cells weighs 30lb., or 23lb. for two lamps. The lamps are fixed in a case similar to an ordinary watch-case, and in the sketch three are shown, one on either side of the destination-board and one roof-light. The former have duplex reflectors and consequently act as signal lights.

In the Provinces many of the omnibuses and tramcars are being fitted with these lamps, and in London about 500 omnibuses are either completed or in course of being similarly equipped. Some of these are, we understand, to be supplied with a rearlight and a pedestal lamp on the outside, rising from the roof at the back of the driver to supply light for outside passengers to read by, also acting as a signal light. The lamps are 15in. diameter, with 12in. reflectors. The reflector is patented as an advertising device, the income from which enables the "Zenith" Company to supply their lights at a very small charge per omnibus. Instead of selling the apparatus outright, the Company provide the entire outfit, including accumulators, lamp frames, switches, and inspectors' lamps, for a small weekly rental, and meet the omnibuses at stated hours and given places each day, when a few moments suffice for changing the spent cells and replacing them by others freshly charged.

For bicycles, an 8-volt accumulator is fitted in a leather case with flexible cords, enabling the lamp to be placed at any part of the machine and at any angle.

CORRESPONDENCE.

CONCENTRIC WIRING.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I am glad to see in Mr. Sydney Walker's article in your issue of April 7th, a statement of the case against "Concentric Wiring," and beg you will afford me space to reply.

The only objections urged are briefly as follow:—

1st. There should be no metallic sheathing around the insulation of conductors.

2nd. There should be no contact with "earth."

3rd. Disturbances to ships' compasses.

4th. Alleged possibility of fire.

That it is necessary for the duration of a cable that there shall be "no metallic conductor outside the insulating material" I emphatically contravene. A sound, solid-drawn lead sheathing (as used over concentric cables) seems to me to be the most efficient means of securing the desired durability.

How it can have a positively contrary effect is not at all apparent. If Mr. Walker means that cable makers cannot make reliable sheathed cables, then I shall leave the cable makers to deal with him. Reliable cables of this type by several makers are on the market.

With regard to the second objection,—Mr. Walker is not alone in his objection to "earth" any system of conductors. But those who object most and fight hardest against earths—low-tension supply-station engineers—are finding the task too much for them. As the networks extend and larger numbers of

Hosted by Google

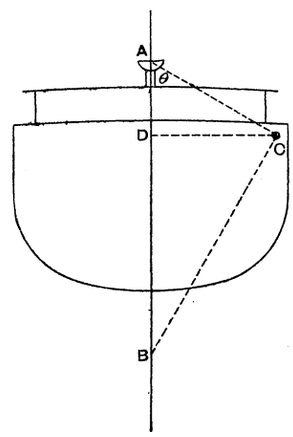
consumers are connected, the difficulties increase, as they have done in America, where to avoid incessant breakdowns the middle wires on their three-wire systems have been put permanently to earth. On this side of the Atlantic there are several authorities who are strongly in favour of the same practice. Where the attempt is made on a three-wire system to maintain the insulation of all three conductors, the maximum E.M.F. between any of the conductors and earth is, say, 220 volts, and if one outer wire becomes earth and a leak develops on the other, electrolysis may proceed with destructive results. If the middle wire be earthed then the maximum E.M.F. available to produce electrolytic action is halved. While if the middle wire be earthed and concentric wiring used on each side, the sheathings being connected to the middle wire, then the *maximum* E.M.F. available to produce electrolytic action is only that due to the loss of volts along the middle wire. The difference of potential along the middle wire may be kept down to a very low figure without additional expenditure of copper by increasing the section of the middle wire at the expense of the outer wires. The same method may be applied to the outer concentric conductor on a two-wire system. For example, a maximum drop of, say, 10 volts is to be allowed; then the inner wire may be so proportioned that there shall be eight volts drop in it, the copper saved from the inner wire being added to the outer wire, in order to keep the maximum difference of E.M.F. between any two points upon it—or between any point upon it and earth—within two volts.

The earthing of the middle wire is, however, so important and so complicated a question, that I much prefer not to involve concentric wiring in it at present. And while pointing out its bearing on the subject, I would distinctly discourage any attempt to force the solution of the problem by pressing the claims of concentric wiring in this relation.

Leaving this problem of the earthing of the middle wire to solve itself—as I believe it shortly will—I am content to hold in abeyance the discussion of the application of concentric wiring in this connection. It is for isolated installations of all kinds that I now urge the use of concentric wiring. During a large experience of it extending over seven years, I have never heard of a single instance of trouble—ever so slight—arising from the earthing of the outer conductor.

The third objection, relating to ships' compasses, is, when applied to concentric wiring, usually much exaggerated. Concentric wiring is often stated to result in the same disturbance to compasses as single wiring. This is not so in fact. But in arranging concentric conductors in relation to compasses on board ship it is well to assume that it is so.

The following is a formula (proved experimentally to be correct) which I believe is due to Dr. Bottomley, for calculating the disturbance of a compass needle by a current flowing in a single conductor.



$$\text{Deflection in degrees} = \frac{2\frac{1}{2}C}{D},$$

where C = current in amperes,
D = distance in feet from needle to conductor, if conductor is directly above or below needle.

If conductor is placed in such a position as shown in diagram

$$D = \frac{AC}{\cos\theta} = \text{distance A B.}$$

By a judicious arrangement of main conductors and the use of double-insulated concentric branch conductors in the neighbourhood of compasses the maximum possible disturbance of the compass may be kept within one-fifth of one point, while the greatest probable disturbance (due to any ordinary combination of lights) would not exceed one-twentieth of one point. He is a smart quartermaster who steers a vessel within these limits. A very large proportion of the ships lighted by electric light are single wired, and it is long since any disturbance of compasses has been reported. The position of the dynamos has often a much more important bearing on the compasses than the method of wiring.

Lastly, with regard to the fire risk. I do not wish to exaggerate the fire risk of electric lighting. That the risk is very small where the work is properly carried out, is proved by the fact that no fire due to electrical causes has occurred in any building where the ordinary precautions now well understood are observed. But I need not suggest the many ways in which a fire *might* occur, even in a well carried out system of double wiring. And I reassert that concentric wiring carried out with proper conductors and fittings entirely abolishes the fire risk. I have with much patience created artificial faults of many kinds in concentric conductors in the endeavour to communicate fire to inflammable material placed around the conductor, but always without success. I would ask Mr. Walker, with regard to the fire communicated by "a virtually concentric" cable, whether it is within his *certain knowledge* that the cable formed part of a system of concentric conductors with "earthed" return. It seems to me more probable that the conductor formed an armoured portion of a single or perhaps of a double-wire system. If this were the case a leak might take place from the inner conductor to the sheathing and from the sheathing to the ship's ironwork (an occurrence impossible with concentric conductors). The spark would thus be external to the sheathing. It is quite a common and most reprehensible practice to use in the holds and machinery space of single-wired ships, armoured cables or conductors drawn into iron pipes. The danger of such a practice is obvious. Single wiring cannot be too sharply condemned.

Mr. Walker's last sentence—"Never hide your connections in damp places; make them as large as you possibly can, and *repair the work the damp has accomplished as frequently as possible.*"—(the italics are mine), is surely a strangely ingenuous admission of the weakness of the methods which he advocates.

Why not protect your insulation and connections against damp by a hermetically-sealed metallic sheathing and abolish the absurd necessity of "frequent repairs"?—Yours, etc.,

56, George-square, Glasgow. SAM MAVOR.

CONDENSING FOR ELECTRIC LIGHT STATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I must entirely disclaim any intention of making comparisons of coal consumption in the two cases given. It is quite obvious that the form of the load curve, and the relation of rate of output to boiler power in use at any time throughout the day have great effect on the proportions of coal used for engines to total coal burnt. The two cases were given one to confirm the other; and considering that one figure was for the winter and the other for the summer, and that exchange of dates might be followed by exchange of figures, and that the difference is only one forty-second, either may be taken as typical.

The table will be more easily interpreted if for "ratio condensing to non-condensing plant" be read "proportion of total non-condensing plant replaced by condensing." As the engine hours vary from year to year independently of the variation of the number of units, an approximate idea of the saving is all that is possible and all that is required. The statement has a limited application in that it assumes the straight line curves for condensing and non-condensing to be parallel. This is only true for a given non-condensing in the case of a particular condensing, *i.e.*, when the expansion is the same in both cases. The saving would be greater if the expansion were carried further in the condensing engine.

Hosted by Google

The table shows that if two-fifths of the non-condensing plant be replaced by condensing, the saving is about 12·8 per cent., and the saving only reaches 16·9 per cent. if the whole of the plant be replaced; but in the former case the total boiler power could be decreased by 8 per cent., while in the latter it could be diminished 20 per cent.

I was not endeavouring to settle the question. You agree with me that this is only possible when local conditions are known. But I thought, and think, the table useful in a discussion as to the relative importance of partial and complete condensing plant, and that it might suitably follow your admirable leader.—Yours, etc., REGINALD WOOD.

THE PROTECTION OF THE ELECTRICAL INDUSTRY IN FRANCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with pleasure in the last issue of your esteemed journal, your allusions to the article of M. Haubtmann, in *l'Electricien* of 8th April.

Long before my colleague, I raised this very question in the same journal in its issue of January 21st last, p. 56, in a short article entitled "Outlets to be sought for in the Argentine Republic." The contribution was signed "D," the initial letter of my name.

You will see, if you will kindly revise the article and take note of my opinions, that I protest with great energy against prohibitory protective tariffs, after having shown by examples from the annals of commerce that such tariffs are always disastrous. For a long time I have sounded the alarm in the columns of the economic press, and my conviction becomes more deeply rooted every day, and it is in the name of these principles that I take the liberty of addressing you this letter which you may publish if you judge it useful.—Yours, etc.,

April 17, 1893, Paris. EM. DIEUDONNÉ.

Extract from Article.

[We are not partisans of the outrageous protection which at present reigns in France. It is without a doubt profitable to a few electrical firms, at least it must be thought so judging by the efforts of the Chambre Syndicale des Industries Électriques to obtain a rise in the customs duties, but it is injurious to the industry at large and to the consumer. . . . Certain French firms fear foreign competition. Why? This implicit admission of commercial impotence is pitiful! But it is understandable. People want to live quietly upon an ancient reputation, without being harassed by the constant necessity of keeping on the crest of the wave of progress. There is the danger. This short-sightedness is a peril bearing in its train baneful consequences. The producer is attached to this "compensatory" system, seeing in it as he does a means of selling an often inferior article at a high price. But what becomes of the consumer's interests in this struggle? . . .].

"A NECESSARY MODIFICATION OF OHM'S LAW."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I find in *The Electrician* of January 13th a reference to my paper on "A Necessary Modification of Ohm's Law," in which the discrepancies in the resistance of a copper wire observed by me and attributed to a change in the dielectric surrounding the wire are attributed to a change in the heat emissivity in the different media. Permit me to give the reasons why I regard such explanation as insufficient.

When I first observed the phenomenon, it at once occurred to me that it might be due to the heating effect of the current and the different rate of cooling of the wire in the dielectrics used, especially as the resistance in petroleum was less than in air. To satisfy myself upon this point, the current strength was varied through a wide range by interposing resistances up to 200 ohms between the battery and the bridge, and in every case the measurements made fell upon the same curve. If the observed difference in resistance were due to a change in the temperature of the wire, this difference should not be the same for different current strengths.

Again, in the article referred to, I mentioned the fact that while a trace of ether vapor in the tube noticeably increased the resistance of the copper wire, it caused a corresponding decrease in the resistance of a silver wire. The same can be said of petroleum, though not to the same extent. The resistance of a copper wire 1 mm. in diameter was less by about 0·8 of one per cent. in petroleum than in air, while the resistance of a silver wire of the same diameter was greater by about 0·04 of one per cent. in petroleum. If the variation in resistance were due to the more rapid cooling of the wire in one medium than in the other, it would seem that both wires should cool faster in the same medium It seemed to me, also, that any wire should cool faster in a liquid like alcohol than in air, and that the heating effect of the current should be in general less marked in a liquid than in air. On the contrary, however, the resistance of the copper wire was greater in every liquid used except petroleum than it was in air.

It is true that the temperature of the the thermometer bulb was not necessarily the same as the temperature of the wire, but that it could have been but little different is shown by the great regularity of the measurements made in the same medium. These measurements were made at all hours of the day, and some of them late at night, and the temperature of the room was probably increasing as often as it was decreasing, so that any difference in the temperature of the thermometer and wire would not always affect the results in the same direction. In the measurements for the curve given in Fig. 1 of the article in the *Phil. Mag.* the measurements were extended over a period of a month's time, while those given in Fig. 2 were made at different times for a period of five days. The very consistent results obtained in this way also answer what seems to me to be a more serious objection, namely, that the temperature of the comparison coils might be different from that of the wire.

It accordingly seems to me that I may be pardoned for useing the expression "necessary modification of Ohm's Law." I am not unaware that Ohm's law is supposed to apply to a conductor only when its physical state has been kept unchanged. In these experiments, however, I have been unable to see how any change in the physical state of the wire, except a change in temperature, could be brought about by changing the dielectric around it, especially when the dielectric is not known to exert any chemical action upon the wire, and when its pressure remains unchanged. That the differences in resistance which I have observed are not due to temperature changes seems to me to be also well established. If this be true, the strength of a current is not necessarily inversely as the resistance of the conductors in its circuit, if by that resistance is meant a quantity depending only upon the nature and physical condition of the conductor itself.

That the phenomenon has not been observed before is not remarkable when the extreme smallness of the quantities observed is taken into consideration. True it is that many of the best measurements made differ among themselves by quantities quite as large as the differences observed in these experiments, but it has been the custom to attribute these differences to temperature changes. So far as I know, no one else has ever looked for a change in resistance due to a change in dielectrics.—Yours &c.,

Palo Alto, Cal., April 4, 1893. FERNANDO SANFORD.

[We still think that the method used for measuring the temperature of the wire was a very crude one. The common method is to deduce the temperature from the observed resistance of the wire, and until our esteemed correspondent can devise an independent sensitive method of measuring the temperature *of the wire*, we fear he will be unable to establish his point.—Ed., *E.*]

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1893 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is NOW READY. This useful book contains over 1,000 pages, and several new and handy features have been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

TENDERS INVITED.—The Town Council of Winchester are prepared to receive specifications, plans, and estimates for lighting the streets and public buildings of the City, and also for private lighting. A premium of £30 is to be paid for the scheme which is considered the most suitable. Some further particulars are given in our advertisement columns, and printed conditions can be had of Mr. Walter Bailey, Town Clerk, The Guildhall, Winchester. The specifications have to be in by the 20th instant.

——— Our advertisement columns contain a notification that the Burgomaster and Aldermen of Liège, Belgium, invite tenders for the installation in that city of a system of electrical distribution. Copies of the conditions of tendering and all other information may be obtained, and plans may be seen, at the Bureau des Travaux Publics, Annexe de l'Hôtel de Ville, Liège. Tenders will be opened on June 15th.

——— Our readers are reminded that tenders have to be in not later than 10 a.m. on Friday next, for the various work required under their Electric Lighting Order for the Town Council of Aberdeen.

——— May 13th is the latest date for applications from companies or firms willing to undertake and carry out the Provisional Order of the Bedford Urban Sanitary Authority. Applications must be sent in to Mr. T. S. Porter, Clerk to the Authority.

——— The Ministerio de Ultramar, Madrid, will up to May 6th receive tenders for the installation and working of a telephone exchange at Santiago de Cuba.

TENDERS ACCEPTED.—The Gas Committee of the Aberdeen Town Council have agreed to accept the tender of Messrs. Stiff and Co., London, for porcelain insulators, the amount of the tender being £200, on condition that the time limit penalty clause in the contract is agreed to by Messrs. Stiff and Co., otherwise the contract will be given to the Glasgow house of Messrs. Doulton and Co.

TENDERS RECEIVED.—The Works and Lighting Committees of the Brighton Town Council issued special reports on Tuesday. The Works Committee recommend that the tender of Mr. J. T. Chappell, for the extension of the engine house, the erection of testing rooms, coal store, &c., and other works in connection therewith at the Corporation electricity generating station, North-road, for the sum of £2,839, be accepted. Five tenders were received, ranging from £5,595. 2s. 1d. to £2,839. The Lighting Committee recommend the acceptance of the following out of forty-six tenders sent in :—

	£	s.	d.
Mr. E. Danks, for supplying and setting three Lancashire boilers	1,475	0	0
Messrs. Yates and Thom, for supplying and fixing steam and water system and piping with feed pump	1,295	0	0
Messrs. Latimer, Clark, Muirhead and Co. (Limited), for supplying and fixing steam dynamos and motor dynamos...	4,894	4	0
Messrs. Crompton and Co. (Limited), for supplying and fixing lamp canopies with switches, &c., for lighting the King's-road	545	0	0
Messrs. Crompton and Co. (Limited), for supplying 45 Crompton and Pochin arc lamps, for lighting the King's-road	766	13	0
Messrs. Latimer Clark, Muirhead and Co. (Limited), for rewinding the armatures of the dynamos now in use at the generating station	450	0	0
Total	9,425	17	0

PERSONAL.—The officials of the Indo-European Telegraph Company and other friends of Mr. Frederick Moll, the secretary and accountant of the Company, entertained him at dinner at Bargens' Restaurant, Coleman-street, London, E.C., on the 8th inst., to celebrate his quarter of a century's service with the Company. Mr. Moll was presented with a silver epergne, suitably inscribed, and a pair of claret jugs, subscribed for by the whole of the staff.

APPOINTMENT VACANT.—The Lighting Committee of the Wolverhampton County Council require a resident electrical engineer. Further particulars appear in our advertisement columns, and applications must be sent to the Town Clerk by May 6th next.

BANKRUPTCIES.—An equalising and second dividend in the estate of Mr. Rankin Kennedy, electrical engineer, late of the Carntyne Electric Works, Glasgow, will be paid at Messrs. Dunlop and Murray's, 82, West Regent-street, Glasgow, on and after May 27th. ——John Herbert Gale, of the Old Vicarage, Stanton Drew, and 25, St. Stephen-street, Bristol, india-rubber merchant and electrician, has been adjudicated a bankrupt.

RE BARNES AND LOW.—Messrs. Bewley, Crump and Deeks, of 6, Lombard-court, Gracechurch-street, E.C., invite the creditors of Albert Moor Barnes, trading as Barnes and Low, at Exhibition-road, South Kensington, to send in their claims promptly. The meeting of creditors, which was to have been held this day, has been postponed till Friday next, the 28th, at Winchester House, Old Broad-street, at 2:30 p.m.

ELECTRICAL ACCESSORIES COMPANY (LIMITED).—This Company remove into their larger premises, at 110, Charing Cross-road, W.C., this week, and will have on show a large and varied assortment of their manufactures. The move is one in the right direction, and will doubtless result in increased business.

ELECTRIC SIGNALLING.—A system of signalling by means of electricity has been specially designed by Messrs. King, Mendham and Co., of Bristol, for the Clifton Rocks Railway, where water-power is used for hauling up the cars, which convey any number of passengers up to eighteen. If the number of passengers in both upper and lower cars is unequal, it is necessary to admit water into a tank on the upper car till it overbalances the lower one, but if the number of passengers in the upper car is equal to that of the lower one, this will establish a balance enabling the hauling system to be worked. In order to convey to the engineer at the top the number of passengers travelling by the lower car, an ingenious arrangement of contact, by which the conductor of the lower car is able to signal up to the top conductor the extra number of passengers to be provided for to establish a balance, has been devised and is at work. The signals are received in succession upon a signal board, and an electric bell rings at each fresh indication, and the engineer is thus able to provide for sufficient water being admitted into the tank to take the car down, and when it is ready a signal is sent down intimating that the car is starting. A local buzzer is then inserted in the circuit, by the sound of which it is known that a distant bell is ringing, and the indicators are arrested by the act of transmitting the "starting" signal, so that the apparatus is in perfect readiness for the next journey. Separate electrical contact and indicator boards are provided for each set of cars, and a double set of batteries ensures proper working of the whole system. When a car reaches the lower end of the tunnel the water in its tank is automatically discharged and is pumped up to the top, the height of water being shown at the bottom by means of an electric water level.

CONCENTRIC WIRING.—Messrs. J. D. F. Andrews and Co. inform us that Messrs Sharp and Kent are introducing concentric wiring into St. Botolph's Church, and that this system is being employed in several other places in the City.

MESSRS. HODGES AND TODD.—Mr. Percy W. O. Hodges has joined this firm, who are adding civil and mechanical engineering departments to their business. Additional premises have been taken in Red Lion-street, W.C., the offices remaining at Turnmill-street, as hitherto.——The firm send us a price list of ammeters and voltmeters manufactured by them.

MESSRS. J. H. HOLMES AND CO.—This firm have just completed one of the largest size "Castle" dynamos, capable of supplying current for nearly 4,000 8-c.p. lamps. This machine is to be coupled direct to a Willans patent compound vertical central-valve engine of 200 I.H.P. The firm have also just completed the generating plant for lighting the North-Eastern Railway Company's Hotel at York, and have been busy with a large number of medium-sized plants for some time past, including a special system for lighting some of the fast trains on the Midland Railway.

"THE ENGINEERING MAGAZINE.—This magazine, which is so well known in America, and with which many of our readers in this country are acquainted, has now found a British habitation. The magazine can be obtained from *The Electrician* offices, Salisbury-court, London, E.C., price 1s., or 12s. per annum post free. The number for April commences Volume V., and contains fully-illustrated papers of considerable interest to English engineers. Included in the April number are articles on "The Industrial Problem in Australia," "A Decade of Marvellous Progress," "English and American Railways," "The Dearness of 'Cheap' Labour," "Refrigeration from Central Stations," "The Past and Future of Engineering," &c., &c., and included in each monthly number is a fairly complete index of current technical literature. The magazine will be on sale at Messrs. Smith and Sons' bookstalls throughout the country on the 28th inst. The April number consists of 136 large 8vo. pages in addition to the Technical Index, which is detachable.

Hosted by Google

AYR.—The Chairman of the Town Council recently inspected the electric lighting installation of Southampton, and has presented his report to the Board. The Burgh Provisional Order expires in August next, and the Clerk has been requested to make inquiries on the subject of electric lighting generally. A special Committee has also been appointed to deal with the matter.

BEDFORD.—At a meeting held last week it was decided to hold a large public meeting to discuss the question of the electric light in the borough, to which an expert was to be invited to put the citizens in possession of facts and figures on the subject.

BOWDON (CHESHIRE).—The Local Board has given instructions for the official seal to be affixed to the form of agreement prepared by the Manchester Edison-Swan Company, and to the modifications in the Provisional Order, which have been suggested by the Board of Trade.

BURNLEY.—The extensive building, known as the Oddfellows' Club, at Keighley Green, Burnley, is to be lighted by electricity. It is the largest institution of the kind in the town, and has thousands of members.

BURTON.—The Town Council having decided to apply for powers to borrow £69,000 for sewage and electric lighting purposes, a Local Government Board inquiry has been held on the subject. It will be remembered that Messrs. Hammond and Co. and John Fowler and Co., Leeds, have secured the contracts for the supply of plant and apparatus. Mr. Ramsden explained the scheme to the Commissioners, and intimated that only a slight deviation from the original compulsory scheme was contemplated.

CANTERBURY.—The transfer of the Provisional Order obtained by the Town Council to the Brush Electrical Engineering Company (Limited) is officially notified.

CHESTERFIELD.—The Water and Lighting Committee have received an intimation from the Gas Company, that in contracts about to be entered into for lighting the borough by gas a considerable increase is to be made in the charge for lighting, cleaning and extinguishing, Alderman Wood, who presented the report, stating that the Gas Company have adopted this means of squeezing the Corporation, as they had no power under their contract to charge more for the gas per thousand than was already charged. The Committee had received a number of letters from electrical engineers offering to advise the Council in the matter of the electric lighting of the borough, and it had been resolved to accept the services of Mr. Shoolbred, of Bradford, and he has been asked to attend an early meeting of the Committee. A circular will afterwards be distributed to a number of the consumers of light in the town, asking them the amount of support they are prepared to give to a scheme of electric lighting. Alderman Wood stated this had been found the most effective manner of ascertaining the amount of support likely to be given to such a scheme, and he instanced a case in Lancashire where a similar canvas had taken place, resulting in the putting down of a much larger plant than had originally been anticipated, owing to the very large number of favourable replies to the circular received.

CRIEFF.—The Local Authority have received a report from a Manchester electrician upon the subject of the introduction of the electric light to the district, for which it is proposed to use water power. We understand that the report states that for an outlay of about £3,000, and an additional outlay of £2,000 for accumulators, an almost complete installation can be secured. The situation is especially suitable for water-power work, and the electric lighting scheme is very favourably received by the ratepayers.

DUNDALK.—As the contract with the local gas company for lighting this district expires in July, Mr. Maxwell, a member of the Town Commissioners, considered it a fitting opportunity for endeavouring to obtain tenders for lighting the town by electricity, but after considerable discussion it was decided to advertise in the local journals for gas lighting, as hitherto.

DUNDEE.—The electric light is so keenly appreciated in Dundee that quite a storm arose at the last meeting of the Police Commission as to the position of the arc lamps in the principal streets, more than one member apparently feeling aggrieved that his establishment had not been selected as a point for the erection of one of the posts. There can be no doubt that an arc lamp forms an exceptionally good advertisement, to say nothing of the actual value of the light radiated through the upper windows.

FALMOUTH.—Notwithstanding considerable opposition, it has been decided to invite an expert to advise the Urban Sanitary Authority on the subject of the introduction of the electric light.

HENLEY.—At the last meeting of the Corporation a letter was read from the local Gas Company notifying them that they were unable to entertain a proposal for a reduction in the charges made for gas for public lighting. An attempt was made to bring forward the subject of the electric light for the town, but without avail.

HOOLE.—Dissatisfaction is expressed by members of the Local Board at the peremptory refusal of the Chester Gas Company to entertain any suggestion for a reduction in the price of gas supplied for public and private lighting, and the Chairman of the Board stated at the last meeting that if the Board can get sufficient support from the inhabitants steps will be taken for obtaining the electric light.

IPSWICH.—The Paving and Lighting Committee of the Town Council last week were engaged in a discussion on the subject of the electric light. Mr. Pratt, a member of the Lamp Committee, stated that he held an application for a large number of lights from many of the principal shopkeepers in the town. It was generally agreed that the light was becoming very popular, and that the matter would have to be dealt with promptly. After some discussion it was decided to refer the matter to the Sub-Committee already appointed, to which additional members were added.

JAMAICA.—The Kingston City Council have decided "that before fixing the signature of the Mayor and Council to the contract with the Electric Lighting Company, a committee of three members be appointed to report upon the correctness of the terms." A movement is on foot to considerably extend the installation.

LECTURES.—To meet the widespread demand for information on electrical subjects, lectures are still being delivered in various parts of the country. Among the most recent, we note one by Mr. Robert Hammond, at Blackpool, by Mr. Jerritt, at Plymouth, by Mr. J. Anderson, at Thurso, and by Mr. Flood, at Jarrow.

LEICESTER.—With reference to the contracts received for supplying the necessary plant, &c., for the electric scheme, these contracts were referred to an expert, with a view of settling some points in dispute. It is stated that he has given a decision confirming the recommendations of the Gas Committee, and there is, therefore, little doubt that the contract will be entered into with the Brush Electrical Engineering Company.

LIMEHOUSE.—Prof. H. Robinson has been instructed by the Limehouse District Board of Works to prepare a report on the subject of the electric lighting of the district. At the last meeting of the Board it was suggested that co-operation with the Poplar district would be advisable, and it was pointed out that the latter district had obtained its own Provisional Order.

MIDDLESBOROUGH.—A sub-committee has been appointed by the Town Council to obtain information of the cost of lighting the municipal buildings by electricity.

MILL LIGHTING.—The extensive sawmills and offices of Messrs. Moss and Co., of Hoxton-street, London, N., have been fitted throughout with the electric light. Arc lamps are used for the yards and mill, and incandescents for the offices.

NEWCASTLE.—The installation of the electric light at the extensive premises of the Co-operative Wholesale Society, in Thornton-street, is now complete, and the contractors, Messrs. Ernest Scott and Mountain, have handed the plant over to the representatives of the Society. The work has been completed under the superintendence of Mr. J. Thompson, of Newcastle. Between 1,100 and 1,200 lamps are fitted.

NOTTINGHAM.—Progress is reported regarding the building operations for the large central station to be erected on the site acquired by the Corporation between Talbot-street and Wollaton-street, and it is expected that a contract will shortly be let for the erection of the necessary buildings.

ROTHESAY.—As previously notified in these columns, it has been decided to defer any further consideration of the subject of electric lighting for the present. Messrs. Mavor and Coulson have reported on the subject, and a supplementary report has been prepared by Mr. Turnbull. It was agreed that the information the Committee had obtained would be available any time, but that for the present the cost was prohibitive.

SHERBORNE (DORSET).—An interesting exhibition of electrical appliances of domestic and commercial utility was held last week by the King's School Field Society. A large quantity of apparatus was on view, and the exhibition created much interest in the district.

SOUTHAMPTON.—The tender of Messrs. Donnison and Parmiter, of Manchester, for £167, has been accepted by the Free Library Committee for the electric light fittings required for their new building. There was a difference of £190 between the lowest and the highest tender—that of Messrs. J. Sugden and Co., of London, £375. The next lowest to that of the accepted tender was from Mr. F. M. Newton, of Taunton, £171. 5s. In all, nineteen tenders were received.

Hosted by Google

TIVERTON.—At the next meeting of the Town Council a resolution will be brought forward by the Electric Lighting Committee on the subject of the report presented by Mr. Siddalls, together with a separate report on the advisability of utilising the water-powers of the rivers Exe and Lomann, prepared by Mr. Frank Christie, of Chelmsford. A digest of Mr. Siddall's report appeared in our last issue.

TUAM.—Communications have been received from engineers and others on the subject of electric lighting for the district, and the Board of Guardians are considering the subject.

WAKEFIELD.—For some time past a sub-committee of the Corporation have been collecting information regarding the electric light, and the subject is now likely to receive further attention. The Town Clerk will probably have instructions to apply for a Provisional Order.

WORCESTER.—The plans and estimates for the proposed buildings for the generating station at Powick were discussed at the last meeting of the Watch Committee, and it was decided to recommend the Council to apply to the Local Government Board for an additional sum of £9,000 to complete the scheme.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

March 23, 1893.

6,170. J. MEIR. Manchester. Improvements in apparatus for forming earthenware electric switches and the like.

6,200. W. AITKEN. Glasgow. A new or improved protector for electric insulators, also applicable as a wire guard.

6,205. R. WOOD. London. Improvements in method of and apparatus for distributing and regulating the distribution of electricity for lighting and motive power and other purposes.

6,225. SIEMENS BROS. and R VON FISCHER-TREUENFELD. London. Improvements in ground sockets for tubular posts for telegraphic and other purposes.

6,233. E. DU BOIS. Improvements in electric clocks.

6,241. T. DUNCAN. London. Improvements in electricity meters or motive devices for measuring single and multiphase electric currents.*

6,254. A. L. SHEPARD. London. Improvements in electric arc lamps.

March 24, 1893.

6,282. J. PHILLIPS, junr., and T. C. LEWIS. Sheffield. Electrical fire or temperature alarm.

6,295. T. STOBER. Manchester. Improvements in and relating to electric incandescent lamps.

6,306. S. E. NIELSEN. London. Improved electric current meter.

March 27, 1893.

6,439. T. E. MARSH and T. G. POOLE. London. Improvements in electric switches.

6,446. J. SWIFT. London. An apparatus for showing the phenomena of the expansion of crystals and other substances by heat produced by electric force.

6,468. SIEMENS BROTHERS and Co. (LIMITED) and J. NEBEL. London. Improvements in electric arc lamps.

6,470. B. J. B. MILLS. London. Improvements in electrical measuring instruments. (A. E. Kennelly, United States.)

6,475. J. J. RICKARDS. London. Improvements in means and apparatus for varying the speed of electro-motors or the electromotive force of electro-dynamos.

6,477. S. O. COWPER-COLES. London. Improvements relating to electro-plating and apparatus therefor.

6,478. E. THOMSON. London. Improvements in and relating to dynamo-electric machines and motors, and to circuits for use in connection therewith.*

March 28, 1893.

6,517. S. B. JENKINS. Birmingham. Induction system of electric heating and for other uses.*

6,532. G. KAPP. London. Apparatus for recording excess currents in the working of electro-motors for traction and other purposes.

6,551. T. G. HALL. London. A pyro-electric generator, an apparatus whereof such generator is an element, a process carried out by the aid of such apparatus, and a new compound gas made by such process.*

COMPANIES' MEETINGS & REPORTS.

Eastern Extension, Australasia, and China Telegraph Company (Limited).

The thirty-ninth ordinary general meeting of this Company was held on Wednesday at Winchester House, Old Broad-street, under the presidency of Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. F. E. Hesse) read the notice calling the meeting and the minutes of the thirty-eighth ordinary general meeting, and the report of the Directors was taken as read.

The CHAIRMAN: Before asking you to approve of the report, I shall as usual go over some of the details, and give you such information as I think it is well that you should possess. The gross receipts for the half-year under review have amounted to £247,766, against £243,658 for the corresponding period of 1891, showing an increase of £4,108, notwithstanding the heavy loss on exchange (£11,692) shown on the credit side of the revenue account. For the whole of the year the loss has amounted to £20,000, but since the close of the half-year steps have been taken, as explained in the report, to avert, as far as possible, any loss in the future from this cause. The working expenses have amounted to £91,768, against £74,314 for the corresponding period of 1891, showing an increase of £17,454, of which £16,000 is caused by the "expenses attending maintenance of cables" having amounted to over £38,000 in the past half-year, against £22,000 in the corresponding half-year of 1891. Of this large increase, however, £15,796, or nearly the whole of it, is due to cable expenditure, as shown in Abstract C of the accounts, by which is meant not only the various lengths of cable actually used on cable repairs and maintenance but also the "writing down" of cable in stock to a reasonable figure. Another exceptional item is the large payment of £6,030 shown on the debit side of the revenue account for income tax, which not only embraces the tax for the particular period but includes £2,071 for the arrears which accumulated pending the decision of the Special Commissioners on the Company's appeal against the surcharges made by the surveyor of taxes, together with adjustments of the account. Comparing the figures for the whole year, the results are as follows:—Gross receipts for 1892, £494,754, against £508,536 in 1891, or a decrease of £13,782. The working expenses for 1892 have been £171,049, against £145,790 in 1891, or an increase of £25,259. The net revenue for 1892 was £250,843, against £286,986 in 1891, or a net decrease for the year of £36,143, which is accounted for by the explanations already given. The usual interim dividends have been distributed during the past year, making, with the dividend proposed to be paid to-morrow, a total payment of 5 per cent. for 1892. It is also proposed to pay a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the past year. (Cheers.) The balance of £75,843 has been carried to the general reserve fund, which now stands at £509,732, made up as follows:—Amount of reserve at end of 1891, £428,842; interest during the year, £14,004; value of cable recovered from Rangoon-Penang section, after crediting capital expenditure with £20,000, £22,324; and balance from revenue during 1892, £75,843—making a total of £541,013, less cost of Singapore-Penang triplicate cable, £25,974, and partial renewal of the Shanghai-Foochow cable, £5,307, leaving the fund, as already stated, at £509,732, after having expended £1,162,000 out of revenue on cable renewals, duplications, and triplications since the formation of the Company, and thus greatly strengthened and improved the value of your property. A further drawing of 353 of the Company's Five per Cent. Australian Subsidy Debentures took place on the 6th inst. for payment at par on July 1st next, when the debenture debt, which originally stood at £640,000, will be reduced to £285,000. The Company's repairing ships have, as usual, been busily employed during the past half-year; but owing to most of our system being duplicated, the traffic has not been materially affected, except with China and Manila, which by our route are practically dependent upon a single line of cable between Singapore and Hong Kong. The weakness of this section has long been recognised, and much negotiation has from time to time taken place with the Governments of Hong Kong and Singapore and the Home Government with a view to strengthening it, but hitherto the necessary monetary assistance to enable the Company to lay a second cable has not been forthcoming, and no practical action has therefore resulted. Lately, however, negotiations have been revived on a new basis, namely, for the Company to receive special privileges in lieu of subsidies, and as soon as the negotiations are completed we shall at once proceed to have manufactured and laid an alternative cable between Singapore and China, connecting the valuable coal fields and harbour of Labuan *en route*. This will also practically provide telegraphic communication with British North Borneo, and lead to the development of new traffic, besides greatly strengthening the Company's position in the East. (Applause.) All the various sections of the Company's system are now in good working order. With reference to the Australian tariffs, which I have frequently alluded to on previous occasions, I am glad to say that the increased rates to Australia, referred to in the last report, came into operation on January 1st last, with the result that the additional 9d. has not caused any appreciable falling off in the number of words transmitted, consequently the increased rate is practically all profit, and will diminish the loss for the current year under the Government guarantee arrangement to a comparatively small amount. At the Postal and Telegraph Conference, recently held at Brisbane, the delegates of the guaranteeing colonies expressed themselves perfectly satisfied with the arrangement, and a motion was carried in favour of continuing it. The reductions of tariff to New Zealand and between Australia and New Zealand, which were also referred to in the last Report, took effect from the same date, and up to the end of last month have resulted in an increase of the international traffic of 88 per cent. out of 300 per cent. required to recoup the loss arising from the reduction, and of 51 per cent. out of 188 per cent. required in the inter-Colonial traffic. In other words, the Company's one-fourth risk of loss, based on the first three months' experience of the reduced tariffs, is at the rate of £3,188 per annum, and the New Zealand Government's three-fourths risk of loss is £9,563, but as the traffic shows signs of considerable vitality, and the commercial depression in New Zealand appears to be now passing away, it is not anticipated that the actual losses at the end of the year will be anything like so serious as these figures would represent. Since the close of the half-year under review, the Chinese and Russian telegraph systems have been connected and opened for traffic, with the result that the land lines are now competing with the cables for traffic to the cable ports as well as to the interior of China. As, however, the rates fixed by the Russo-Chinese Convention for the land lines are exactly the same as by the cables, although for the present a slightly higher sum is collected, owing to the depreciated exchange, for messages transmitted by the cables from the cable ports, and as, moreover, the working of the land lines is found to be somewhat irregular and unsatisfactory, the competition, as far as we can see, is not likely to prove serious. We trust, however, that a satisfactory working arrangement will eventually be arrived at with the Chinese administration. I have now given you a very careful statement of what has occurred during the last six months, thinking it is always right that, as far as lies in our power, we should furnish you with every information in order that you may see what we have been doing, and understand what we are going to do in the future. We have always felt that the more confidence that exists between the Directors and the shareholders the more successful the Company will be. I think that policy has been fully appreciated by you all, and I believe that there are very few Boards of Directors who can come before their shareholders as we do to-day, and show you a more satisfactory result of the year's working than we have done in the statement I have just made to you. Nevertheless, I may tell you that there is still a great deal yet to be done. It requires very close attention, and also a good deal of knowledge to work out satisfactorily all those problems that come up from time to time between the Australian colonies and the Mother Country. As you know, the Australasian colonies are becoming great powers in themselves, and I may here record the first instance of a thoroughly united action on the part of all the colonies in favour of our telegraph system. Hitherto, at least one has always stood aloof, and the one that has looked on probably more than any of the other colonies has been Queensland, whose sympathy with our action we have done everything possible to enlist. We expect a great deal more from that colony than it has yet given us. Having given them practically all the advantages which every other country derives from our great system, which now permeates the world, they have never yet said a thankful word to us, but have wished, above all things, to get some other Company to come forward, lay an alternative cable to that which exists, and give them half rates without their paying anything in return for it. That is the policy Queensland has been pursuing in the past. Possibly they have now begun to see things from a more reasonable point of view, and recognise that the Company has been doing everything it could to meet public requirements. Only the other day we showed our sympathy for them in their recent misfortunes. I hope sincerely that the little cloud that has hung between us for so many years will disappear now that unanimity has been established, as I have just mentioned. With all the other colonies we have the most happy relations, and I may add something which is almost unusual—that there is nothing existing at the present moment that is in the least objectionable between us. (Hear, hear.) Not even a complaint from these colonies. As you are aware, they have been labouring for the past two years under very severe commercial depression. We see from day to day indications of that in the banks which are having to close their doors; but the land does not run away, the spirit of the people remains, and while I believe that they have been somewhat speculative, the country will, I feel sure, eventually resume the same career of prosperity which it enjoyed for so many years. That will greatly benefit the Company, our system being an accurate indicator of the trade of the country. Notwithstanding all the depression which is abroad at the present moment, we have done rather better than worse this half-year. I referred in my earlier remarks to the proposed alternative China cable, which is the only section we have at the present moment not duplicated. The China and Manila traffic represents a considerable portion of our revenue, and if anything were to occur to the existing cable a very large amount of traffic would pass from us. For many years past we have been in negotiation with the local and home Governments with a view to enabling us to put down another cable, but commercial affairs have not been very prosperous, and we have found every succeeding Govern-

Hosted by Google

ment rather more difficult to get money from than its predecessor We do not propose spending any money out of capital in connection with this cable; and if we can carry our negotiations to a successful issue with the Government, the result will give us such security as will add largely to the value and strength of our property. (Cheers.) Those of you who read the papers attentively will have seen the references to the laying of a cable from New Caledonia to connect with Queensland. This has been very much encouraged by the latter colony, which I believe has promised to contribute £2,000 towards it, New South Wales promising a similar amount. It is, however, like a drop in the ocean; and while we should be very glad to see the New Caledonia cable laid, the principle upon which it is being established is not likely ever to make it a successful cable. Still, under any circumstances, it will always be a feeder to us, to a certain extent. The cable, I believe, is to be laid by the French; it must be managed by the French; it must be engineered by the French; and it must be worked in detail by the French. There is to be no English blood or element connected with it, so I do not see any very great future for it. (Cheers and laughter.) I wish I saw a large future, because we are always disposed to encourage feeders such as this, which, if it does us no good, will certainly do us no harm. That cable is supposed to be the first link in a chain across the Pacific. I can tell you without any hesitation that to carry a cable across the Pacific would require a subsidy of about £100,000 a year. That being so, you may depend upon it that it will never be done by French capital, and it is not likely to be done by English just yet. If, however, it is ever done for strategical purposes, I think that we are the people who are likely to carry it out. I daresay you have read in the papers lately a suggestion from a gentleman—who takes a great deal of interest in these things—to the effect that the Government should buy up the cables. In fact, the matter is now on the paper of the House of Commons, and it will come up some day. What I would say about the subject generally is this, that it is a question which will involve something like 35 to 40 millions sterling, and I should like to know where that money is to come from. (Voice: Not from the present Government.) If the money is found you may depend upon it that the shareholders of this Company will participate in the benefit accruing from it, as we shall be able to show what we have done for this Company in improving the value of our cables and our position generally; and if the Government should desire to acquire our undertaking, I am sure you will not object to our selling it to them at the price we shall ask. At all events, when the time comes, your property will not be less but more valuable. (Applause.) I think I have now told you all that is good for you to carry away, as you now know almost as much about our affairs as your Directors do. I think we can congratulate you on the report, and on the thoroughly satisfactory working of the whole of our system, and I am only expressing the opinion of my colleagues when I say that we are very proud of the position we hold to-day in the City of London as a great and influential Company. I beg now to move the following resolution:—

"That the report and accounts of the Directors now submitted be received and adopted, and that a dividend be now declared of 2s. 6d. per share, together with a bonus of 4s. per share, both free of income-tax, payable on the 20th instant, making, with the previous distributions, a total payment of 7 per cent. for the year 1892."

The Marquis of TWEEDDALE: I beg to second the motion.

The CHAIRMAN: If any gentleman wishes to put any question to me I shall be glad to answer it to the best of my ability. After a pause, and no shareholder rising to address the meeting, he continued: Then, gentlemen, I will ask those of you who are in favour of the motion which I have just read to signify the same in the usual manner. To the contrary. Carried unanimously.

The Marquis of TWEEDDALE: Gentlemen, I think that the motion which I have now to make is one that will be most acceptable to you all, for it is the re-election of our Chairman as a Director of the Company. You know him nearly as well as I do, and, therefore, I do not think it is necessary for me to say a single word in support of the motion. As you are aware, Sir John Pender has proved himself one of the most able, active, and prosperous Chairmen in the City of London. I think I may take advantage of the opportunity which the moving of this resolution affords me to express the hope—which I am sure you will agree with—that he may long be spared to occupy this position. (Cheers, and hear, hear.)

Mr. FRANCIS A. BEVAN: I have very much pleasure in seconding the motion.

The resolution was then put to the meeting and carried unanimously.

The CHAIRMAN: Gentlemen, I beg to thank you for the honour you have done me in again re-electing me. Next year, I think, we shall attain our majority—we shall be 21 years old. I think we have grown very fairly, and that we have got a good physique, and, moreover, that we have all the spirit and "go" to make a new departure from our 21st year if necessary. I hope that there are many here who will see this concern continuing to prosper when I have left it, but as long as I have strength I am going to remain at work with it. The next resolution which I have to propose is:—

"That Sir James Anderson, who now retires by rotation, be and is hereby re-elected a Director of this Company."

I deeply regret the absence of Sir James Anderson, who is ill, and in a state of health which entirely precludes him from being among us; but I know from the warm and hearty interest he has always taken in the whole of the telegraph system that while he is at home to-day on a sick bed his heart is in the midst of us. I beg to propose this resolution, and I shall have very great pleasure in conveying to him the news of his re-election.

Mr. GEORGE G. NICOL: I second the resolution.

The motion was put to the meeting and carried unanimously.

The CHAIRMAN: The next resolution relates to the auditors, and must come from the body of the meeting.

Mr. JOHN NEWTON: I have much pleasure in proposing—

"That Mr. Henry Dever and Messrs. Welton, Jones, and Co. be and are hereby re-elected auditors for the ensuing year at a remuneration of £100 each."

Mr. KENNETH ANDERSON: I beg to second the resolution.

The CHAIRMAN put the motion, and, having declared it carried unanimously, said, "That concludes the business of this meeting."

Mr. BURGESS: I think we should be wanting in gratitude if we did not propose that the very best thanks of the meeting be given to our worthy Chairman and the Directors. I think if you were to go through the whole of London you would not get a more devoted Chairman or a better set of Directors than we have.

Mr. JOHN NEWTON: I second the resolution with much pleasure.

The motion was carried by acclamation.

The CHAIRMAN: I am very much obliged to you for the resolution you have just passed, and for the kind words which were said by the gentleman who proposed it. On behalf of my colleagues and myself I can only say that we warmly appreciate and value all the kind words that come from your side of the table, and I hope that we shall always continue to merit your confidence and support.

Phonopore Company (Limited).

The fourth annual meeting of this Company was held on Wednesday at Winchester House, under the presidency of the Right Hon. Sir Mountstuart E. Grant Duff (Chairman).

The SECRETARY (Mr. Charles Isaac) having read the notice calling the meeting,

The CHAIRMAN said he felt some diffidence in coming before the shareholders on that occasion, because there must be a great many of them who knew very much more about the earlier history of the Company than he did. Many of them had been connected with it since its existence, whereas he knew nothing about it before August 31st last. As they were aware, when the Company had been started for some time, it was found that they were approaching the end of their resources, and a considerable amount of additional capital was raised upon preference shares, some of those who advanced the money joining the Directorate He confessed, looking over the past, that if he had known that the amount of their liabilities was so large as it turned out to be, he would not have joined the Board. He should have stipulated that before he took part in the Direction they should have entirely settled with the inventor. If that had been done before they raised the additional capital, he should not have had to announce that there would shortly be a call of half-a-crown upon the preference shares. Referring to the accounts for the past fifteen months, ended December 31st last, he said they represented hardly anything except preliminary expenses in getting their ship out of harbour. There were items, amounting to £4,500, which would not appear again. One of the principal events that had occurred since the reconstitution of the Company in August last was the acquisition of Mr. C. E. Spagnoletti as Managing Director, whose fame was widely spread amongst those people, in this and other countries, to whom the application of electricity to the purposes of life was of great interest. When he (the Chairman) came behind the scenes he was a great deal disappointed to find that they could not work over as large an extent of wire as he had hoped. He found they could work perfectly well from London to Bristol, but not from London through to Plymouth. In foreign countries there were a great many places they wished to assist to communicate with each other, and which were further apart than London and Bristol. Mr. Spagnoletti had done all he could to perfect the instrument so as to be able to work unfailingly over long distances. He wished he was able to say that Mr. Spagnoletti had quite succeeded, but all he could venture to say was that he believed himself to be thoroughly on the way to success. When they could work unfailingly over long distances he was quite sure they would have a very large market for the phonopore instruments in a great many countries, to say nothing of the very considerable advantages to be obtained by the application of them to submarine telegraphy. Passing to what they could do and were doing, he said they were working with perfect success from London to Bristol, and from London to Birmingham on the Great Western; from London to Cambridge on the Great Eastern, and to places on other railways, including the Great Northern. After stating that the phonopore block connector—an instrument affording additional advantages for establishing telephonic communication upon the block wires from station to station while the wires were being simultaneously used for the transmission of telegraphic signals—was a thorough success, the Chairman said that now they had got free from their important liabilities he hoped that when they met again he should be able to give a much more cheering account of the prospects of the Company. In conclusion, he moved the adoption of the report.

Mr. E. F. WEBSTER seconded the motion.

Mr. LANGDON DAVIES said shareholders had heard at previous meetings over and over again everything the Chairman had stated on that occasion. He moved as an amendment that the meeting be adjourned till that day three weeks to enable the Board, after conferring with a group of shareholders, to report the result.

Mr. FELLOWES seconded the amendment.

Mr. POLLARD deprecated any such amendment as that proposed, now that that they had obtained the services of such an able practical electrician as Mr. Spagnoletti.

Mr. SPAGNOLETTI, in response to the meeting, offered a few remarks as to the prospects of the Company. He said a prejudice existed on the

Hosted by Google

part of some of the railway companies against the phonopore instrume nts owing to the unsatisfactory manner in which they had worked in the p ast He was able, now, however, to obtain letters of recommendation from some of the companies which would be of great assistance to them. In his opinion, the great future for the phonopore lay in the foreign business, which at present they could not take in hand. They were now in communication with several Governments and foreign companies, and if they could only work the distances they required there would be a profitable business in that direction. Everything now was beginning to bid fair for making good business progress.

The amendment was negatived and the report adopted.

The retiring Directors, Mr. A. B. Isaac and Major-General J. Shaw Stewart, were re-elected

Indo-European Telegraph Company (Limited).

The following is the Directors' report for 1892, which is to be presented to the members at the meeting to be held at Winchester House on Friday, the 28th inst., at 1 p.m. :—

The Company's revenue from all sources for 1892 amounted to £117,479 13s. 10d., as compared with £116,699. 3s. 1d. for 1891, showing an increase of £780. 10s. 9d. The expenses were : on commercial and general account, £31,960. 8s. ; on maintenance account, £30,188. 8s. 3d. ; total, £62,148 16s. 3d., as against £61,108. 12s. 10d. for 1891, an increase of £1,040 3s. 5d. Deducting the above expenses, taking credit for £5,983. 15s. 4d. brought over from 1891, and debiting income tax, there remains the sum of £60,057. 16s. 11d. From this amount £10,000 has been placed to reserve, and that sum, together with £10,625 amount of interim dividend, have to be deducted, leaving a balance of £39,432. 16s. 11d.

The Directors now propose the declaration of a dividend for the six months ending December 31st of 17s. 6d. per share, making, with the dividend already paid, 6 per cent. for the year, and a bonus of 20s. per share, both free of income tax, making in all 10 per cent., carrying forward £7,557. 16s. 11d. to the credit of 1893.

The reduced tariff with the Australian Colonies, introduced on May 1, 1891, under agreement with the Colonial Governments, has undergone a slight augmentation with the object of diminishing somewhat the rather considerable losses occasioned. The Directors trust that the still largely reduced tariff at present in force may be enabled to be permanently established.

The Directors, on a careful review of the whole of the circumstances, do not think it necessary in the case of such a small undertaking to apply the machinery of the Forged Transfer Acts.

The former Director-General of Telegraphs for Germany, Herr Hake, having retired, has been succeeded by Herr Schffler, the present Director-General. The following Directors retire by rotation and offer themselves for re-election :—C. W. Earle, Esq., and C. Holland, Esq. The auditors, Messrs. C. F. Ford and Co., accountantr, retire, and offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

ARCAS PLATING COMPANY (LIMITED).—The statutory return of this Company, made up to April 3rd, has been filed. Out of a nominal capital of £80,000, in £1 shares, 17,908 shares have been taken up, of which 2,407 have been issued as fully paid. Upon the remaining 15,501 shares 10s. per share have been called, resulting in the payment of £2,593. 10s., leaving £5,157 in arrear.

AKESTER ELECTRIC SYNDICATE (LIMITED).—The statutory return of this Company, made up to February 17, 1893, has been filed. Out of a nominal capital of £15,000, divided into 300 shares of £50 each, only the seven signatories' shares have been taken up, and no calls have been mad on these shares.

CHLORIDE ELECTRICAL STORAGE SYNDICATE (LIMITED).—This Company has filed new Articles of Association, in which the Directors are given as follows :—William Mather, M.P., of Salford Iron Works, Manchester ; Edward Hopkinson, Salford Iron Works, &c. ; and Hardman A. Earle, of Victoria-street, Westminster, S.W. (Managing Directors) ; G. Annesley Grindle, of Great Winchester-street, London, E.C. ; the Hon. James J. Fellows, of Saxon Hall, Palace Court, Bayswater, London, S.W. ; Edward Tuck, of Paris, France ; and William W. Gibbs, of Philadelphia, U.S.A. The registered office has been removed from Abchurch-lane, E.C., to 8, King-street, Manchester.

HOUSE-TO-HOUSE ELECTRIC LIGHT SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to March 16th, has been filed. The nominal capital is £350,000, divided into 57,900 ordinary, 100 founders', and 12,000 preference shares of £5 each. 8,322 ordinary shares, 100 founders', and 4,291 preference shares have been taken up, and the founders' and 1,000 of the ordinary shares have been issued as fully paid. Upon the remaining 7,322 ordinary and 4,291 preference shares the full amounts have been called, resulting in the payment of £57,915. £150 is still owing on account of 50 of the preference shares.

LIVERPOOL ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to March 10th, has been filed. The nominal capital is £300,000 in £5 shares, of which 40,000 have been taken up. Upon 10,000 of these shares the full amounts have been called, and upon the remainder a call of £3. 10s. has been made. The calls paid amount to £175 130.

ROGER DAWSON (LIMITED).—An agreement, made March 10, 1893, between Alfred Roger Dawson, of St. Margaret's, Portmore Park, Weybridge, Surrey, electrical engineer (the vendor), Arthur R. Cobbett, Charles E. Tomlin, John H. Jenks, and the above-named Company, states that till recently the vendor carried on, in partnership with Mr. A. Rashleigh Phipps, the business of an electric light engineer and contractor, in London, and that the partnership had been dissolved, Mr. A. Rashleigh Phipps being released from all liabilities. The vendor owes Mr. Tomlin £11,664. 16s. 2d., Mr. Cobbett £6,526. 14s. 3d., and Mr. Jenks £115 12s. 10d., and as these creditors are willing to accept certain shares and debentures in the Company in payment of these sums, it is agreed that the vendor shall sell his business to the Company for £10,000, payable £7 in cash and £9,993 in fully-paid shares ; that the vendor shall be Managing Director for seven years, with a salary of £5 per week, in addition to his remuneration as an ordinary Director ; that Mr. Cobbett shall accept 4,900 fully-paid £1 shares and £1,626. 14s. 3d., and 2,499 vendor's shares ; that Mr. Jenks shall accept 100 fully-paid shares ; and that Mr. Tomlin shall accept 100 Six per Cent. Debentures of £100 each and £1,664. 16s. 2d. in cash, and 2,999 vendor's fully-paid shares.

PHOSPHOR BRONZE COMPANY (LIMITED).—The annual return of this Company, made up to March 10th, has been filed. Out of a nominal capital of £150,000, divided into 15,000 preference and 15,000 ordinary shares of £5 each, 8,375 preference and 7,335 ordinary shares have been taken up. Upon these shares the full amounts have been called, and all calls (£78,550) paid, and £11,560 has been paid on forfeited shares.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The numbers are announced of a drawing of 177 Five per Cent. Debentures of £100 each of the 1884 issue. These debentures will be paid off at par on July 31st next at Parr's Banking Company and the Alliance Bank, Bartholomew-lane, E.C., and interest will cease after that date.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended April 16th were £861, as against £734 for the corresponding period of last year, being an increase of £127. The total receipts for half-year amount to £13,717 against £12,495 in the corresponding period of 1892, being an increase of £1,222.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company give notice that payment by warrant will be made on May 1st of interest for the half-year ended April 30th, on the Four per Cent. Mortgage Debenture Stock. The transfer books will be closed from April 27th to May 1st, both days inclusive.

GREAT NORTHERN TELEGRAPH COMPANY (LIMITED).—The working account of this Company for the year 1892 is published, and the Directors recommend a final dividend of 7s. 2d. per share, making in all 8 per cent. for the year 1892, the amount actually paid for dividend during the year being £129,166. 13s. 4d. ; £83,333. 6s. 8d. is added to reserve and renewal fund (which now amounts to £806,327. 10s. 5d.), £2,777. 15s. 7d. is contributed to the pension fund of the staff, and a balance is carried forward to the current account of £45,666. 18s. 9d. The general meeting takes place on Saturday, April 29th.

LONDON PLATINO-BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have decided, after placing £1,182 to the reserve fund, to recommend at the forthcoming general meeting a dividend of 4s. per share, free of income-tax, being at the rate of £2 per cent. for the year 1892.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—The annual meeting of this Company takes place at Winchester House this day (Friday) at 12 o'clock.

NEW SHANGHAI ELECTRIC COMPANY (LIMITED).—The report of the Directors of this Company has been presented to the shareholders at the meeting held at Shanghai on the 28th ult. The Directors report a satisfactory working during the twelve months ended December 31st last; the balance of income over expenditure allowing a distribution of 7 per cent., and a liberal allowance for depreciation of plant and apparatus. Only a small addition had been made to the arc lighting of the districts supplied by the Company, the demand for incandescent lighting had necessitated a large extension of the Company's plant, upon which no less than 15,000 tls. had been expended in 1892, which had been met by a loan guaranteed by the Directors. The plant would, doubtless, be working to its full capacity in a short time. Many of the public buildings and the principal hongs in Shanghai are now lighted electrically, and private house lighting is extending in a most satisfactory manner. The total number of incandescents run by the Company up to the end of the year 1892 was 1,269, and when the total number of lights on order were installed, the number would be 2,895. The Company were supplying plant and material for private installations, and to many steamers calling at the port. The operations of the Company were seriously hampered by insufficient capital, and it is probable that an addition will be made to the capital of the Company in the near future. The Directors have no objection to offer to the proposed purchase of the plant, property, and business of the Company by the Municipal Council, and await the action of that body without anxiety.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The Directors of the Company have decided, after placing £15,000 to the reserve fund and £6,674 to the debenture redemption fund, to recommend at the forthcoming general meeting a dividend of 4s. 6d. per share, free of income tax, making, with the interim dividend paid November last, a distribution of £2. 10s. per cent. for the year 1892, carrying forward £2,829. The traffic receipts for the week ended April 14, 1893, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegrap Company (Limited), were £3,137.

Hosted by Google

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have decided to recommend the undermentioned dividends for the six months ended December 31, 1892, viz., 6s. per share on the first and second preference shares, and 6s. per share on the ordinary shares, placing £1,600 to reserve, and carrying forward £1,430. The receipts for the two weeks ended April 15th were £2,789 as compared with £2,656 for the corresponding period of last year. The December receipts, estimated at £5,219, realised £5,275.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 780.—Vol. XXX. FRIDAY, APRIL 28, 1893. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

We regret to announce that the illness from which Sir James Anderson has been suffering for some months past has assumed a serious aspect; and at the moment of our going to press we learn that his condition is critical.

There was little that was new, but much that was too true, in Prof. Kennedy's lecture before the Royal Institution last Friday. In discussing the "Possible and Impossible Economies in the Utilisation of Energy," Prof. Kennedy exemplified, as many others have done before in the same place, that a thorough popular treatment of an important subject is far more interesting and useful than the serving up of brand new discoveries in a sauce of half-cooked theories. Figures and technical matters struggled hard to get in front, then seemed shy of the audience, and retired. The chief points of the lecture were directed against unscrupulous persons, such as "those who will tell you that they can get twice as much energy out of a pound of coal as anyone else can," and all the available missiles—Carnot's function, for example, and the doctrine of the conservation of energy—were hurled at their heads. A source of energy, we were told, might be likened unto a metalliferous ore, in which, there being only a certain percentage of useful stuff, it was foolish to attempt to get more than that percentage out. It was not the fault of the blast furnace—it was Nature's "fault"—that we did not get beyond a certain yield of metal.

Prof. Kennedy showed that was not the fault of the steam-engine, for example, that its efficiency could not be raised to anything like 100 per cent. This argument which ran through the discourse and served to hold together many a hard idea, must not, however, be pressed too closely. It has only a relative application, for in no source of energy is there an absolute limit of available percentage (under 100 per cent.) as there is of metal in an ore. Coal, relatively to a steam-engine, may not be able to yield more than 30 per cent. at the best; but, if the coal is turned into producer gas, its theoretical limit in a gas-engine becomes two and a-half times higher; and there is no denying that a process may be discovered whereby the availability may be approximated closely to 100 per cent. This need not—in fact, would not—be a heat engine. Considered thermodynamically, the human body is an engine which has an everyday efficiency far higher than the highest limit fixed by Carnot's function. That is because the human body is not a heat engine, pure and simple. The *impossible* economies relate only to the special processes of utilising energy, and do not depend upon rigidly exclusive general principles.

The relation of prime to working costs is an important point in this connection, which was not hinted at in the lecture. The highest limit of efficiency which may be fixed for the steam-engine is only the highest when we avoid all reckless expenditure in designing the engine and follow economic laws in the use of materials. Even for any special process of utilising energy, the impossible economies are less physical impossibilities than commercial ones. Perhaps this was what Prof. Kennedy had in his mind when he said that "as an engineer he did not believe in any impossibilities except perpetual motion and the transmutation of metals!" Lord Kelvin and Prof. Crookes, by-the-bye, might enlighten him as to his second *non credo*.

But the sin of wasting the energy of nature was laid, not so heavily at the door of Nature herself, as at that of the bad engineer. Woe unto you, ye bad engineers, who build engines so much worse than the best, for the world's annual balance-sheet of energy consumption would show only one-third of its present figure for the same amount of work done if every engine were brought up to the standard of the present working best. "The difference in economy between the worst and the best engineering is greater—far greater—than that between the actual best and the theoretically possible best." Considerably half our possibilities consist in improving up to the level of the actual best, in bringing the laggard majority up to the forefront of the fight. Improving the best is a far more difficult, and far less hopeful, matter.

In *The Electrician* for December 9, 1892, we described some experiments by M. Janet on the discharge curves of condensers, which showed very clearly the time oscillations in the potential and charge. In a recent number of the *Comptes Rendus*, M. Janet continues his investigation, and shows how from these curves the relation connecting the potential with the charge may be obtained. If the condenser for these rapid oscillations behaved simply as if it had a capacity, the relation in question would be a straight line, the ratio between the two quantities being constant. The curve obtained, however, encloses an

Hosted by Google

area, and is analogous with, though not the same shape as, the hysteresis curve connecting magnetism with magnetising force. The writer appears to infer that this curve proves the existence of true electric hysteresis between the electric charge and the electric force. All it really proves, however, is that a loss of energy occurs in the dielectric. Similarly in the magnetic case, when the curve connecting magnetism with current is deduced from two curves, one connecting magnetism with time and the second connecting current with time, it is found that the hysteresis curve obtained differs considerably from the ordinary Ewing curve. It encloses a larger area, and, instead of being pointed at its extremities, it is always rounded. The difference in the two areas is due to eddy currents, and there would be no proof of the existence of true hysteresis if the only evidence in favour of it was the rounded curve obtainable in this manner. Static experiments alone can prove the existence of true hysteresis.

THE theorem of Professor POYNTING, concerning the path of the energy movements in the electromagnetic field, has recently been applied in an interesting manner by M. BIRKELAND, to explain some hitherto obscure phenomena presented by Hertz oscillations. Some of the more recent advances in this subject have depended upon the consideration of the mode in which the electrical disturbances die away. By applying POYNTING'S theorem to the case of a Hertz oscillator, M. BIRKELAND has shown that the rate of subsidence of the electromagnetic energy in a given space depends upon the shape and position of the conductors in the neighbourhood, and that it consequently varies with the place considered. This serves to explain the difference found between the values of the logarithmic decrement obtained experimentally, and by calculation from the general configuration of the oscillator; since the latter quantity is only an approximate value, in obtaining which the losses of energy in local circuits due to the resistances of the various parts of the apparatus are neglected. M. BIRKELAND has also offered a likely explanation of some reflection phenomena observed by MM. SARASIN and DE LA RIVE. According to these investigators, when electromagnetic waves are reflected at the end of a wire the stationary waves formed have the nodes differently situated for the electric and magnetic waves. This is explained by showing that the path along which the electric energy travels is quite distinct from that along which the magnetic energy moves. M. BIRKELAND'S note is printed in the *Comptes Rendus* for April 17th.

M. DESIRÉ KORDA has rediscovered the fact, announced some years ago by Professor TROUTON, that it is possible to increase the frequency of an alternating current by exciting the fields of an alternator with one alternating current, and using a suitably wound armature to produce a second. In Tesla and in three-phase motors the same effect occurs, for the frequency of the current in the short-circuited armature depends on the relative speed of the armature and field, as well as on the frequency of the current in the latter. M. KORDA'S armature is very similar to one devised by MM. HUTIN and LEBLANC, since it is doubly wound, with its two parts displaced so as to be in quarter-phase relation to one another; and it is shown mathematically that the result of this is to produce a current of three times the frequency of that which is used to excite the magnets. But the unsatisfactory feature of the article, which seems characteristic of all mathematical essays on the theory of multiphase machines, is the total neglect of the effect of armature reactions on the field. Moreover, we cannot share the optimism of the writer in urging the advantages of high-frequency currents for practical purposes. According to M. KORDA'S article, which appears in a recent number of the *Comptes Rendus*, the great advantages of avoiding the use of iron, and hence the losses due to hysteresis, in transformers, and also of rendering condensers of small capacity capable of passing large currents, are too well known to need repetition. On the contrary, the tendency of commerce is to reduce the frequency of alternating currents. Condensers are not likely to be much used in future, and transformers without iron are purely visionary.

WHERE simple fractions occur in the course of running text we have frequently used the /, called a solidus or shilling-mark, to avoid unsightly alteration in the "whites" between the lines. Since the discussion on the printing of mathematical symbols which appeared in our columns in October last, we have used it rather more frequently; but we can assure those who advocate such reforms that it has cost far more trouble than it is worth, by creeping into fractions having more than one term in the numerator or in the denominator. We hope that we have, as a rule, succeeded in detecting these in proof, and have not allowed them to appear in our columns. We regret, however, that last week, in an abstract of a Paper by Herr NERZ on the "Construction and Uses of Projectors," this symbol was ambiguously used more than once. It is hardly necessary to give the errata, as careful reading will show that by tan $a/2$, for example, is meant the tangent of half a, and not half the tangent of a.

WE notice this week the action of the Eastbourne Electric Light Company in offering to provide electromotors for ventilating the up-take columns of sewers. The offer has been accepted, and a motor is to be continuously supplied with the current for three months for £5, tests being taken in the meantime on the amount of foul air extracted from the sewer. The introduction of electromotors for this purpose is by no means the first occasion on which mechanical power has been employed for removing dangerous gases. Large blowers and fans have been successfully used for carrying a supply of fresh air through the workings at mines and collieries. As a rule, however, it has been found more economical to adopt a system of ventilation by hot-air currents, a furnace being kept up in the up-take for the purpose of heating the out-going air, and thus creating a draught. A proposal was made some time ago to place a resistance coil at the base of the column of sewer up-takes, and to keep this coil very hot by means of an electric current. Theoretically, this plan would be more efficient than mechanical ventilation, and would offer the further advantage of having no working parts requiring occasional oiling and repair. Practically, however, the mecha-

Hosted by Google

nical method may prove to be the superior one, as in the alternative method the cast-iron column would offer a considerable cooling surface to the heated gases, and would thus lead to a dissipation of much of the energy supplied to the coil. Careful experiments extended over a lengthy period can alone determine the value of either of these systems. It is interesting to note, however, that in the mechanical method the energy which is not turned into mechanical motion by the motor is not altogether wasted; for the heat spent in overcoming the resistances of the armature and field coils, and in turning the spindle in the bearings, will warm the column of gas and assist its ascent. The mechanical device, therefore, offers a composite method, in which the gas is partly got rid of by a fan-thrust, and partly by becoming specifically lighter on account of a rise in temperature.

Municipal electric lighting committees are apparently inaugurating the somewhat hazardous, though we do not say disastrous, policy of disregarding expert advice. As a matter of general principle it would seem decidedly the better course for town councillors to take the advice of their experts on faith, like they do many other things that are beyond their mental jurisdiction, but two recent instances of municipal independence appear to show that perversity has its advantages. Last week the Islington Vestry adopted the high-pressure system in the face of a recommendation to do otherwise. This week the prevailing fashion for high-speed engines notwithstanding, the Leicester Town Council have decided to employ horizontal compound condensing slow-speed direct-coupled engines in their proposed central lighting station. The magnificent Sulzer engines seen at work in the Cologne and Dusseldorf central stations were at the bottom of this stiff-neckedness, but we hope their magnificence will not lead to the order being placed outside the United Kingdom. If horizontal, etc., engines *are* to be the order of the day at Leicester, we feel sure many an English firm could turn out sets quite as imposing in appearance and as economical in steam consumption as any made in Germany. However, whether the plant hail from this country or the Continent, we shall watch its performance with lively interest.

The Leicester Town Council seem to have rather more acquaintance with steam machinery than is usual with such bodies, but a little knowledge is, as usual, dangerous. So glibly did Councillor Billings talk of kilowatts that some inquirer demanded an explanation of the term, and was promptly told that it meant a thousand watts. But "What's a watt?" demanded this inquiring spirit. Alas! he had touched bottom; the united wisdom of Leicester's aldermen was not equal to an answer; the Council was, to put it vulgarly, "stumped." Alderman Priestman, of Bradford, and other municipal magnates, have, indeed, done good service to the electrical industry, but engineering had, on the whole, better be left to engineers, unless we are to have an engineering analogue of the mayor who addressed a meeting, on a recent occasion, on the civilising effects of the advancement of science, and suggested that the lines of latitude and longitude should be taken up and replaced by submarine cables.

It is not often that we have to chronicle in these days the rout of an entire dichotomous Legislature of the orthodox pattern by a group of company promoters. In the Isle of Man, however, both the Court of Tynwald and the House of Keys have had to give up a clause upon which they had set their Legislative hearts, making it compulsory upon the Douglas-Laxey Electric Railway Company to carry goods. The promoters of the Douglas-Laxey Electric Railway stated their willingness to do as much goods carrying as would pay, but the line being mainly a mere pleasure line, they would rather sacrifice their Bill than proceed with it harassed by such an obligation. On the principle that even a paying railway is better than none at all, the Manx Legislature gave way.

The Late M. Van Rysselberghe.—The Belgian Government has granted an annuity of £120 to the widow of the late M. Van Rysselberghe.

Taunton.—A Local Government Board Inquiry was held at Taunton on Wednesday last week, relative to the borrowing of £16,000 for electric lighting.

Blackpool.—The corner stone of the Corporation electric-lighting station, now in course of erection, will be laid by the Mayor of Blackpool to-morrow.

King's College Old Students.—The annual dinner of Old Students of King's College will be held at the Holborn Restaurant on Monday, May 15th, with Mr. W. H. Preece in the chair.

Royal Society.—Amongst the Papers down for reading before the Royal Society yesterday was one by Prof. J. C. Ewart on "The Electric Organ of the Skate: Note on an Electric Centre in the Spinal Cord."

Telephonic Communication in the United Kingdom.—At the weekly meeting of the Balloon Society, held at St. James's Hall on Friday evening last, Mr. A. H. Hastie delivered an address on "Telephonic Communication in the United Kingdom."

Telephone Rates.—The House of Representatives of Missouri has recently passed a Bill establishing maximum telephone rates at £10 per year in towns of over 100,000 inhabitants, £8 per year in towns of between 30,000 and 100,000 inhabitants, and £6 per year in all other towns of the State.

Arc Lighting in St. Pancras.—In spite of the Electricity Committee of the St. Pancras Vestry having twice recommended centre-lighting for Park-street, it has been decided to adopt side-lighting in view of the complaints made with regard to the obstruction to traffic occasioned by the Tottenham Court-road pillars.

Institution of Civil Engineers.—On Thursday, May 4th, at 8 p.m., being the forty-first anniversary of the election of the secretary as an associate, the first "James Forrest" lecture will be delivered by Dr. W. Anderson, F.R.S., M.Inst. C.E., the subject being "The Interdependence of Abstract Science and Engineering."

The General Electric Company.—According to the "condensed balance-sheet" of the General Electric Company (U.S.A.) covering the first eight months of its existence down to January 31st last, its stock and debenture capital now amounts to close on £9,000,000, its net profits for the eight months in question being stated at over £670,000.

Folkestone.—At a meeting of the Town Council last week there was a notice on the agenda "To consider the expediency of introducing the electric light into Folkestone, either generally or over a limited area of the town, and as to terms and arrangements, and generally in relation thereto." After some discussion the motion was carried.

Hosted by Google

Electrical Bills in Parliament.—The Kensington and Knightsbridge Electric Lighting Company's Bill has passed the examiners in the House of Lords. The following Bills have been read a third time in the House of Commons :—Brighton and Rottingdean Seashore Electric Railway Bill, and the City and South London Railway Bill.

Morals of Corporations.—Amongst the Papers read at the last meeting of the National Electric Light Association at St. Louis was a somewhat lengthy dissertation on the "Morals of Corporations," presumably American. We should have thought it possible to have compressed the subject within the briefest limits :—The morals of Corporations ; they have none.

Worcester.—At a special meeting on Tuesday, the Council adopted the recommendation of the Watch Committee to apply for a further £9,000 to build a generating station for electric-lighting purposes. The building was originally estimated to cost £2,000, but a more substantial structure was rendered necessary owing to a change of site and the decision to use water as well as steam power.

Cable Interruptions and Repairs—

Cables.	Date of Interruption.	Date of Repair.
Accra-Grand Bassam	April 11th	April 21st
St. Thomé-Loanda	April 11th	April 25th
Para-Maranham	March 20th.....	—
Paramaribo-Cayenne	April 15th	—
Santiago de Cuba-Mole St. Nicholas	April 20th	—

Huddersfield.—At the meeting of the Town Council last week it was stated, in answer to a question, that applications for the electric current already received exceeded what their present machinery could supply during the coming winter. The Committee were, therefore, obliged, only the week previous, to increase their machinery by one-third. They believed now that their machinery would be ample for the coming winter. Gas at Huddersfield is 2s. 9d. per thousand, and the Board of Trade unit 6d.

The Frankfort Exhibition.—The first volume of "The Official Report on the Electrotechnical Exhibition at Frankfort-on-the-Main, 1891," has now left the press. It is a profusely illustrated volume of 632 pages, and deals not only with the exhibits but with the inception, opening, progress, and close of the Exhibition. The price of the first volume is 20 marks, and Messrs. J. D. Saverländer, of Frankfort, are the publishers. Vol. II., containing an account of the labours of the Committee of Tests, is now being printed.

Electric Transmission of Power in Sweden.—An application has been made to the Swedish Government for a concession to install an electric transmission from the Dal River waterfall at Mansbo to the Norberg mining district, a distance of some ten miles. The power transmitted will, to begin with, be about 200 H.P., and the potential will be about 10,000 volts. The town of Ostersund will also soon have have an electric transmission of power from the Strup waterfall on the Indal River, The distance is about eleven miles, and the pressure is also to be 10,000 volts.

American Transformer Design.—The only features of note in the latest type of transformer now being placed on the American market by the General Electric Company (U.S.A.) are the use of oil, the earthing of the core, and the relegation of fuses, switches, &c., to a separate case. The fuses are covered in with rubber tubing, with a view, it is said, of hindering sparking. The earthing of the core is done mainly with a view to prevent lightning getting into the secondary. The 1,000-watt 52-volt transformer has a quarter-load efficiency of 88·2 per cent., and the secondary drop on full load is 1·21 volts.

Fans for Ventilating Columns.—The Manager of the Eastbourne Electric Light Company has devised a fan which can be introduced into the base of the ventilating columns, and driven by a small electro-motor. The Company having offered to fit the apparatus in the column situated at the junction of Meads and Carlisle Roads, and supply the current to drive the motor for three months for the sum of £5, the Highway Committee have decided to accept the offer, and have instructed the Borough Surveyor to take daily tests of the amount of foul air extracted from the sewer, and report to the Committee as to the value of the apparatus.

Electric Lighting in Calcutta.—It was thought, says the *Indian Engineer*, a few years ago that Calcutta was within measurable distance of the time when it would be possible for the residents of this large city to obtain a supply of electricity for lighting or motive purposes from road mains, as is now the case with gas. And, in fact, as far as the spirit of enterprise was concerned, there was no hitch whatever ; but the obstacle proved to be the absence of State regulations. This want, strange to say, has not during these five or six years been met, and no department seems to concern itself with this very important question. It is surely time that Calcutta should be allowed to choose between gas and oil on the one hand and electricity on the other.

Electric Railroads and Electrolysis.—In a recent leading article our New York contemporary, the *Electrical Engineer*, remarks that, as it has been shown that in many instances the railway currents take to the water pipes and other conductors in the ground by preference, it must be obvious that if the currents can be made to return to the generating point *exclusively* by such conductors without utilising the earth, all difficulty will be obviated. A beginning of this kind will soon be made near Boston, where a special line of feeders will be run from the central power house to the different parts of the city, and will not be connected with the machines at all, but will be connected with the water pipes to the station and with the pipes in all sections of the city.

Telegraph Extension in India.—The Telegraph Department, says the *Indian Engineer*, is pushing forward with considerable energy the opening up of new offices. By April 1st 100 new departmental and combined offices will have been opened in India since the commencement of the year. A large proportion are in Lower Bengal and Madras, in both of which provinces the telegraphs pay better than in others, a result due not only to the fact that trade is brisker than elsewhere, but also that the people are, on the whole, better educated and seem to understand more readily the great advantages afforded by the telegraph wire. Satisfactory as the yearly reports of the department have been in the past, still better results may be looked for in the future. Burma should soon commence to assist in swelling the annual returns, and the Kashmir line, which has already been partially taken over, may also prove a paying concern.

Edinburgh.—After a discussion which lasted almost four hours, the Town Council on Tuesday adopted the recommendation of the Lord Provost's Committee—"that it be remitted to the Committee to carry out the necessary Electric Lighting Works and employ an engineer"—by 20 votes to 10, eleven members of the Council being absent. A local paper expresses itself as follows regarding this decision :—

> If yesterday's division in the Town Council of Edinburgh truly represents the feeling of that body on the electric lighting question, the majority will be assuming a tremendous responsibility in proceeding further on the course now nominally sanctioned. . . . . The Corporation is free to impose its own terms upon the companies, and if these terms are regarded by the companies as too onerous, then some justification might be offered for municipal management. . . . . And would it not also be advisable to obtain—as could easily be done by authority of the Council—an account of the financial condition of companies and corporations in England which have engaged in electric lighting? Such information would be worth the perambulations of scores of deputations, most of whose members do not know the difference between a volt and an ampere.

Leicester.—On Tuesday last the Town Council again considered the report of the Gas Committee (an abstract of this report appeared on page 472 of our issue of February 24th) upon the tenders for an electric-lighting plant, and which recommended that the scheme of the Brush Electrical Engineering Company should be adopted and their tender at the sum of £26,977 accepted, and that application should be made to the Local Government Board for permission to use the land adjoining the Aylestone-road Gas Works as the site for works, and for sanction to a loan of £50,000. Owing to allegations of unfairness in the matter of awarding the contract, Prof. A. B. W. Kennedy was called in to report. In this report Prof. Kennedy stated that the total prices of the Brush Company and Messrs. Ferranti came out as £26,517 and £23,225 respectively. The former firm, however, tendered for considerably larger plant than the latter. In the matter of price it appeared to

Hosted by Google

him, that the costs compared with value were practically the same in the two cases. Each of the firms claimed that it had successfully solved the vexed question of supplying satisfactory alternating-current motors. The two tenders being so exceedingly alike, and the tender of the Brush Company, on the whole, the more advantageous, Prof. Kennedy recommended its acceptance. Prof. Kennedy concluded by saying that he had no hesitation in asserting that "from the engineering point of view the marine triple-expansion engines are preferable to the horizontal compound." After a lengthy discussion, the Brush Company's tender, exclusive of engines, was agreed to.

The Cleaning of Tramway Rails.—At a recent meeting of the Society of Engineers, a Paper was read by Mr. H. Conradi on "The Cleaning of Tramway and other Rails." The author made a few remarks on street-cleaning appliances in general, and the conclusion arrived at by him was, that they do not tend to keeping tramway rails clean, but rather the reverse. He then referred to the regulations enforced by some local authorities which compel the tramway companies to leave their lines in the muddy and dirty condition engendered by the general street traffic unless mud-collectors are used in combination with the apparatus for clearing the rails. He pointed out that, although the combination of a mud-collector with an ordinary street-sweeping machine had been condemned and abandoned, several local authorities still imposed this combination. He also showed how prejudicial to both animal and mechanical traction dirty tram rails were, and described several machines devised for effecting their clearance. The author then described a rail-cleaning machine devised by himself. The apparatus had been fixed to four tramcars at Reading, and had now been in operation for 18 months. He then described several experiments made during the running of the cars, by which it was shown that the tractional resistance met with by a car running on rails cleaned by the previous car was from 25lb. to 30lb. less than when running on dirty rails. He also compared the cost of various systems of cleaning, arriving at the following results :—By hand, once a day, 1s. per mile of single line in the fine season, and 2s. per mile in the severe season. Watering by cart twice a day, 2s. 6d. per mile. By the author's rail cleaner, as often as required, 6d. per day.

Bristol.—The electric lighting of a large part of Bristol will be inaugurated early in September. The engine-room and boiler-house extend the whole length of the central station, and at the rear are coal bunkers, in connection with which there is an elevator which conveys the coal into mechanical stokers fixed to each boiler. Two large 210-kilowatt alternators, and two small ones of 88 kilowatt, are to be used for private supply. These are designed to work at a pressure of 2,000 volts, the current being conveyed by steel-armoured cables to 11 sub-stations in different parts of the city. The arc-light dynamos will each supply a current of 80 amperes at 650 volts to the lamps, arranged 12 in series and 8 in parallel. These dynamos are coupled direct to Willans engines, so arranged that they may be worked condensing or otherwise. The steam pipes are arranged on the ring main system, so that, in the event of a mishap, any section may be cut out without interfering with the general working of the plant. The high-pressure cables are concentric, and the distributing mains triple concentric, the distribution being on the three-wire system. Ordinary single cables, provided with solid-drawn lead sheathing and steel armouring, are to be used for arc lighting. The street lighting will commence at the railway station and extend to part of Clifton, there being 96 arc lamps of 1,500 nominal candle-power placed at intervals of 50 yards on alternate sides of the thoroughfares. It was suggested that the lamps should be suspended over the centre of the streets, but, owing to difficulties with regard to fire escapes, this has been abandoned. In one unusually wide thoroughfare the lamps will be erected in the centre. Mains have been laid in most of the scheduled streets, and 3,800 applications have been received for the light.

Willans Memorial Fund.—It has been thought very desirable by some who knew the late Mr. Willans personally and knew the value of his work, that steps should be taken to aid in perpetuating his name in connection with the branch of engineering in which he so greatly distinguished himself, and in which his knowledge and experiments, always freely placed at the service of everyone, were and still are so useful. It has been considered, after discussion, that the most desirable way of doing this would be to establish a fund from which a premium might be awarded annually or biennially, or at such periods as might be thought fit, for a Paper on such a general subject as the utilisation or transformation of energy, treated especially from the point of view of efficiency or economy. It has been further thought that it would be advisable to ask the Councils of the Institutions of Mechanical and Electrical Engineers to become joint trustees for this fund, and to award the premium in alternate years to the best Paper bearing upon the subject mentioned presented to them in the interval, the premium not to be awarded in case of no paper of sufficient merit being presented. It is proposed that the fund necessary for this purpose should be called the Willans Memorial Fund, and should be collected by subscription, the subscriptions (unless anonymous), being limited to sums not exceeding two guineas. Mr. Alexander Siemens has consented to become treasurer of the Committee for the purpose of carrying out this scheme. Amongst the Committee are Lord Kelvin, Dr. William Anderson, Sir Frederick Bramwell, Messrs. Frank Bailey, Latimer Clark, R. E. Crompton, Sydney Dobson, Bryan Donkin, E. B. Ellington, W. T. Goolden, Druitt Halpin, Prof. George Forbes, Dr. John Hopkinson, Mr. Gisbert Kapp, Prof. A. B. W. Kennedy, Messrs. J. Macfarlane Gray, W. H. Massey, W. H. Mordey, J. F. Moulton, Q.C., Thomas Parker, Prof. John Perry, Messrs. W. H. Preece, J. H. Rosenthal, Prof. W. C. Unwin, and Major-General Webber.

Frequency in Transformers.—"Some years ago," says *Industries*, "there was a very unprofitable discussion as to the relation between the dimensions and output of a dynamo. Professors multiplied the linear dimensions of phantom dynamos by n, and found the output was various fractional powers of n times that of the original phantom before they had tampered with it. The discrepancies were numerous, but they were all due to electricians assuming different conditions. The dynamos might be compared if designed so as to give the same efficiency or the same final temperature. The copper might be run at the same current density, or the magnets at the same induction. If the same induction were employed, the armature of the larger machine, when enlarged to scale, had too many ampere-turns, and so on. Then, again, the larger machine could not reasonably be expected to run at the same speed, so it had to go either with the same factor of safety or the same peripheral speed. Hence, there were so many ways of comparing the machines that the results of the calculations did not agree. We are now threatened with a similar pseudo-scientific epidemic with regard to transformers and frequencies. Mr. Steinmetz calculates that the output of a transformer varies as the three-eighth power of the frequency. Obviously, if a transformer of a given size is to be re-designed with the same weights of iron and copper for, let us say, increase of frequency, it may be designed to give an increased load at the same efficiency, or with the same percentage drop, or with the same total rise of temperature, or with the same light load efficiency, and it will have a different output in each case. Again, there is no reason why in the comparison we should adhere to the same weights of copper and iron. We might vary them, keeping the total weight or total cost the same. We thus have at once pointed out twelve different laws of the relation between the output and frequency of a transformer. If other comparisons are made, such as the same bulk with different weights of copper and iron, and if allowance is made for the relatively smaller volume of insulation on a high-frequency transformer, we obtain still more laws. It is, therefore, sincerely to be hoped the unpractical electrician will not flood the technical Press with calculations as to the relations of output and frequency. He has so far spared us the discussion of the output of a phantom curve of sines transformer whose dimensions have been multiplied by n. Such calculations are quite useless."

ELECTRICITY AS A MOTIVE POWER.*

BY ALBION T. SNELL.

(Continued from page 676.)

(*e*) *General Conclusions with reference to Field-Magnet Design.*—A point to be specially observed before discussing the proportions of iron and copper is that no one design of field is equally well adapted for every size of armature. If cost of production be the ruling factor the single-magnetic circuit type is preferable for armatures up to, say, 12 inches in diameter;

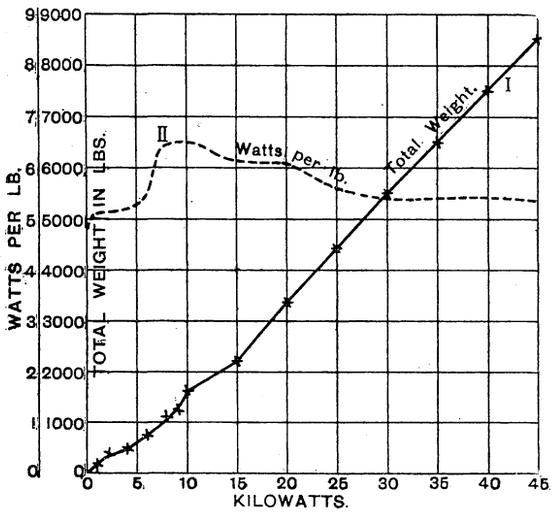

FIG. 11.

from this to 15 inches the double circuit may be used; but from 18 inches and upwards one of the multipolar forms should always be employed.

This feature of dynamo design has not been much discussed as yet; but the author has been led to investigate it when designing large machines. He discussed at length the relation of weight to cost, with varying types of machines, a short time ago. He finds that the curves connecting weight and output, and cost per kilowatt with output, follow

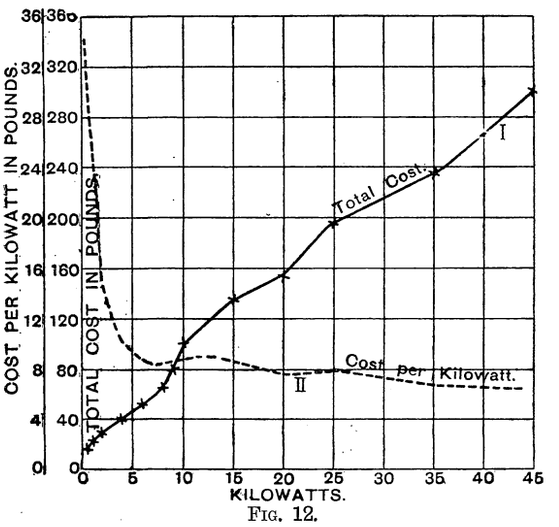

FIG. 12.

very different laws with distinct types of machines. The subject is interesting, but rather outside the scope of this book, and therefore only two diagrams will be given, which show the general shape and order of the curves. It will be seen that the weight and output curve follows practically a straight line law, and that the output of a dynamo or motor is proportional to the cube of the linear dimensions of the machine, practically of the armature diameter and length. (*See* Figs. 11 and 12.)

The question of material has not yet been mentioned, because this is rather a matter of cost and convenience. The necessary sections and corresponding inductions with wrought and cast iron are given in the following tables, and the student can estimate for himself the relative advantages. Practically, with bipolar machines at the inductions usually employed, viz., B''_f = from 77,000 to 97,000 in wrought iron and B''_f = from 45,000 to 50,000 in cast iron, the relative magnet cross-sections should be in the ratio of 3 : 1·6, the effective armature section being taken as unity. Of late, cast steel magnets have been used with some success. The induction curve for cast steel lies nearer to that of wrought than to that of cast iron, and so there seems a probability of its use becoming more frequent.

Table C.

Table giving area of wrought and cast iron to correspond to given inductions in air, assuming all the lines to pass through the iron and none to leak.

Wrought Iron.		Cast Iron.		Air.
Area.	B''_a.	Area.	B''_a.	B.

From George Halliday's "Notes on Designs of Small Dynamo," p. 33.

The shape of the magnet cores is of importance, because the length of the mean turn of the winding is affected thereby. The circle has the minimum perimeter for a maximum area enclosed, and therefore possesses the ideal section; and the square gives, from this point of view, better results than any other rectangular form. Structural considerations, however, carry great weight, and it is found in many designs that a rectangular core, with length equal to twice or three times the depth, most nearly meets all the conditions, in spite of the extra expense in copper.

§ 9. Calculation of the Magnet Details.

(*a*) *Winding Space.*—In the preceding section the relative areas of cross-section of armature and field-core were shown to be in the ratio of 1 : 1·6 for wrought-iron magnets, and 1 : 3 for cast-iron. These ratios are not absolutely the best in all circumstances, but in practice they give economical results. It may be assumed, then, that a type of field is chosen, and that the material has been decided on. The area of the field-magnet cores will also be known from its relation to the area of the armature iron. The open factor at present is the length of core to carry the exciting coils. This cannot be settled without calculation; but a few trial and error determinations will show the minimum length to carry the necessary turns of wire, allowing at the same time the proper area of surface for the watts spent. For bipolar single magnetic circuit machines 0·75 D, for double circuit 0·9 D, and for multipolar fields from 0·4 D to 0·5 D will be very nearly correct for all ordinary designs. And when the other quantities are properly balanced the number of square inches in the surface of the winding, not including the ends, will be equal to about twice the number of watts wasted in heat, or each watt of energy wasted in the magnet windings will be dissipated through a superficial area of two square inches. This is found to be sufficient in machines with windings not exceeding 2½in. in depth. But for large machines a greater margin is preferable if it can be obtained.

(*b*) *Poles and Polar Extensions.*—The next point to determine is the length of the polar cavity. This has already been referred to in § 8, division (*c*), and the practical limits have been given. It may be further noted here that since the magnetic resistance is lowered by increasing the width of the polar cavity, it appears advisable to make the arc embraced as large as possible. But this is limited by the strength of the cross field, which is directly proportional to the extent of the pole pieces. With

Hosted by Google

drum windings the lead of the brushes is comparatively little, as the field disturbance is small, and so the polar angle may be somewhat larger than is permissible if a gramme ring be used. A safe rule is to make the angle 135deg. for drums, and 125deg. for grammes; but both of these figures may require to be slightly modified by the peculiar conditions of the design.* In a well-proportioned dynamo, when the armature is carrying the maximum circumflux for its diameter,† the brushes will require a lead just sufficient to bring them under the tips of the pole piece, so that the lead and the width of the polar cavity roughly depend on each other. The question of lead is, however, very complex, and is affected by so many other points in the design that the author deems it best simply to refer to the above relation. The ratio of area of polar cavity to the cross-section of the magnet core is determined mainly by the induction B''_g in the gap. It is not found economical to push the flux beyond $B''_g = 33{,}000$; and, therefore, neglecting leakage, the ratio of area of polar cavity to core-section will, be approximately, 1 : 2·75 if wrought iron be used, and 1 : 1·6 if cast iron. But there is always a certain loss of magnetism from leakage, and it is necessary to allow for this in estimating the total field core flux. Calling the leakage coefficient v, the relation between the field lines and the armature lines is expressed by

$$N_f = v\,N_a \text{ or } v\,N_g.$$

The assumption that the armature induction is equal to the induction in the gap will not introduce a large error for ordinary designs, and it simplifies matters. The stray field is not constant for every type of magnet, but varies with the armature induction, increasing in value as B''_a approaches its maximum. The practical values of v in the types of machines most in vogue are given in Table D.

Table D.

Table giving approximate values of v, the leakage coefficient, for various types of field magnets.

Type of Magnet.	Open Circuit.	Full Load.
Single magnetic circuit, upright type, Figs. 1 and 2	$v = 1{\cdot}3$	$v = 1{\cdot}32$
Single magnetic circuit, inverted form, Figs. 3 and 3A	$v = 1{\cdot}31$	$v = 1{\cdot}33$
Double magnetic circuit, Figs. 4, 5 and 6	$v = 1{\cdot}4$	$v = 1{\cdot}42$
Four-pole machines, Fig. 7	v = from 1·4 to 1·45	v = from 1·42 to 1·47
" " " 8	v = from 1·45 to 1·5	v = from 1·47 to 1·6
Armour-clad field, Fig. 9	$v = 1{\cdot}2$	$v = 1{\cdot}22$

(c) *The Yoke.*—The yoke is that part of the magnet which connects the cores. It is not usually covered with windings, and is made either in wrought or cast iron so as to suit the design. Generally cast-iron is preferred, since the bed and yoke can, in many cases, be combined in the same pattern. If this device be adopted, as in Fig. 1, care must be taken that the path through which the magnetic flux will principally pass is at least as wide as the area of cross-section of the cores, and usually it is found advisable to make it about 1·2 times larger, if the cores and yoke are of the same material. If the cores be made in wrought and the yoke in cast iron, the latter should be about 1·6 to 2·0 times as great as the former in the area of the cross-section at right angles to the lines of force.

Attention must be given to the joints between the cores and the yoke, that they be truly machined and be in close contact over the entire face.

In machines of the double-magnet circuit type there is no yoke, since the pole pieces are connected directly to the magnet cores; these joints must be carefully made.

In some designs the polar cavity can be bored from the solid iron (*see* Figs. 2, 3 and 6); but in others it is necessary to attach extension pieces, so as to increase the polar cavity (*see* Figs. 1, 4 and 5). But the dimensions of the pole-pieces will in all cases be governed by the rules previously given.

(To be continued.)

THE CONSTRUCTION AND USES OF PROJECTORS.*

(*Concluded from page 715.*)

Source of Illumination.

The arc light is of course generally used now, as it combines with great intensity the nearest approach to a point of light. The spherical form assumed in the above considerations is not a property of this light; the chief source of illumination is the incandescent crater of the positive carbon, the negative carbon emits relatively much less light, and least of all the arc itself; and the negative carbon itself gets in the way of an even distribution of the light emitted. Various methods have been suggested to avoid the losses due to this shadow effect. One of these is to incline the carbons 30° to the vertical, and displace the negative carbon parallel to the positive nearer the object to be illuminated, but this method can only be used with advantage on mirrors of small useful angle such as those of Mangin. For angles over a certain amount, the best arrangement is the arc placed in the axis of the mirror and its superiority is probably, almost certainly, due to the fact that part of the light emitted by the negative carbon falls on the edges of the mirror, and part is reflected

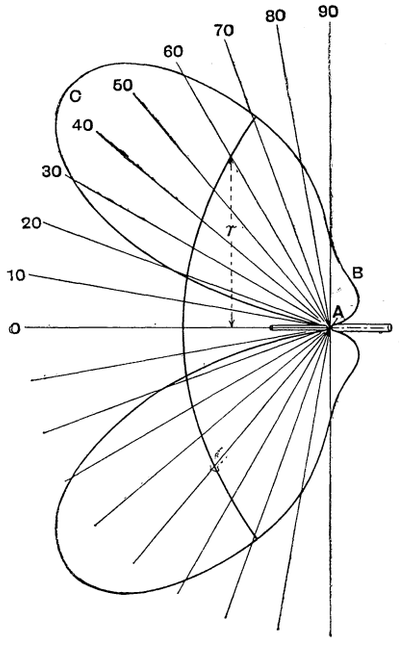

Fig. 5.

from the positive crater on to it. In Fig. 5, A B C shows the intensity curve of a horizontal lamp. If we consider an element of surface Δ of the mirror, it is illuminated by an intensity $f(J)$, which can be taken from the curve; and the zone of the mirror belonging to this element of surface reflects an amount of light

$$L_1 = \frac{f(J)\,2\pi r\Delta}{\rho^2},$$

and if we determine these values for particular points on the mirror, we find that they increase from the centre up to a maximum at an angle ϕ_x, which is larger than the angle ϕ_y corresponding to the greatest value of $f(J)$. Again, if the average amount of light reflected be calculated for increasing values of the useful-angle, it will be found to become a maximum for a certain angle ϕ_z; and this angle will again be larger than ϕ_y. Mirrors which have as nearly as possible this useful angle will have the greatest output. With parabolic mirrors it only remains to choose the proper focal length for a reflector of given diameter in order to secure the greatest possible output.

* Abstract from a Paper presented to the Verein Deutscher Ingenieure by F. Nerz.

Hosted by Google

If the output of mirrors of different diameters is to be compared, all being constructed for the same "useful angle" ϕ, we can substitute for

$$4\pi r^2 \sin^2 \frac{\phi}{4} \cos^4 \frac{\delta}{4}$$

the expression

$$\pi C d^2/4$$

in the above formulæ. The intensity of illumination of a field at a distance e, is then

$$J_2 = \frac{\pi C J d^2}{4} \frac{D^2}{d^2 e^2}$$

whence we see that the diameter of the sphere of light—*i.e.*, the crater—drops out of the formula, which takes the simple form $J_2 = \pi C J D^2/4e^2$;

that is to say, that the intensity of illumination in the field due to the mirror is as great as if it were produced by a source of illumination which has increased from the size of the sphere of light to the size of the mirror without abating in specific intensity.

As the surface of the crater is approximately proportional to the power, but the specific intensity remains, within the limits under consideration, fairly constant, it follows that the brilliancy will not be increased by extra expenditure of power, but only the size of the illuminated field. It follows that as far

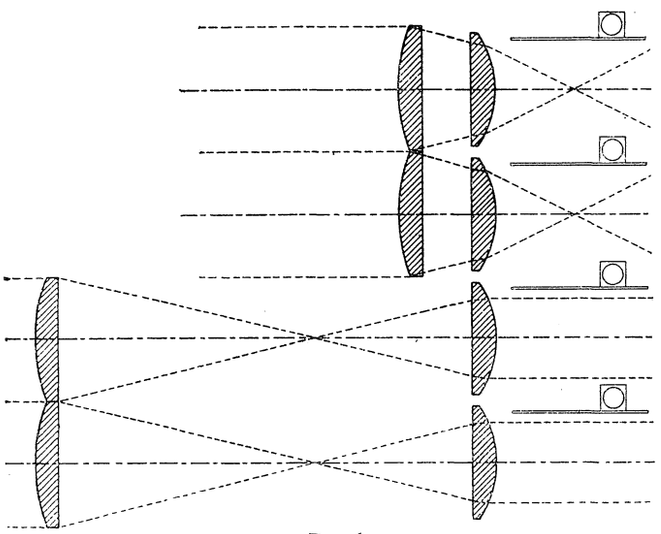

Fig. 6.

as brilliancy of illumination is concerned, so long as concentrated light is used, the efficiency of a projector cannot be increased by increase in current, and the current strength should be chosen for a certain diameter of reflector only by consideration of the "angle of illumination." Thus having determined for a certain projector the proper focal length, the second most important point is to choose the proper current strength in order to produce the maximum illuminating effect for the least expenditure of electrical energy.

Of course there are often points of construction which necessitate deviation from the best possible form of mirror. For use at sea it is not so important to see a ship as far off as possible, but to illuminate the water all round at such a distance that torpedo boats must pass the illuminated zone before coming near enough to do damage, and an instrument to light all round would serve this purpose best; but there is not room, generally speaking, on ship-board for such apparatus, and often in old ships there is not even place for one projector.

To increase the "output" of a projector, as we have seen, it is necessary to increase its dimensions, and practically mirrors may be about 3ft. in diameter; they cannot be larger, firstly, because the working of the guns would damage them and secondly, because they would become too clumsy for use on board. To facilitate the search for torpedo boats, the beam should be spread as much as possible horizontally, and special apparatus is used for this purpose. If the beam has a natural angle of m which is increased to $n°$, the intensity diminishes in the proportion $m:n$, whence we see that the angle of illumination, and hence the current strength, should be as large as possible. It will be seen that under these circumstances the intensity of illumination *can* be increased by increase of current strength, although of course not in proportion to the extra expenditure of energy, but in proportion to its square root.

There is another point to be noted in this connection, that when the current becomes relatively large, it is necessary to reduce the "useful angle" in order to prevent overheating of the mirror, and this is a point of the utmost importance in the design.

The author refers then to the marked contrast observed at the Frankfort Exhibition between the parabolic-mirror search light of Schuckert and Co., and the one with a Mangin reflector by Siemens and Halske. The former firm exhibited a projector having the mirror 166·0 centimetres in diameter—the largest on record. The lamp took 150

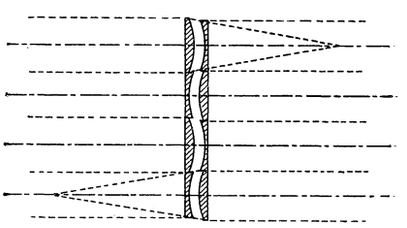

Fig. 7.

amperes and about 60 volts, corresponding to an output of about 12 H.P. in light. The light was seen 71 kilometres (about 40 miles) distant quite plainly, its "ratio of intensification," D^2/d^2, being nearly 4,000—that is to say, the effect was as if the projector were replaced by an arc lamp of 222,000,000 c.p., using a current of about 500,000 A! Another projector was for use on shipboard; its mirror was 91 centimetres in diameter, and the lamp (arranged like the other for 150 amperes) took 120 amperes; this apparatus was provided with a means of varying the horizontal dispersion of the beam between 6° and 45° by simply turning a wheel. The difficulty of changing glasses in front of a projector is naturally well-nigh insuperable, owing to their great weight and surface, and the new apparatus is, therefore, a very important improvement. There was also fitted a signalling apparatus of the "venetian blind" type, so arranged that it could be permanently fixed to the projector without interfering with its working.

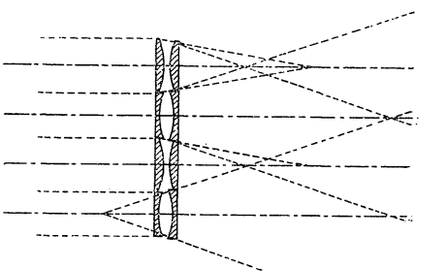

Fig. 8.

The dispersing apparatus consists of two frames behind one another, having an equal number of cylindrical lenses; the one behind has lenses of greater focal length than the front one. When the glasses are distant from one another by an amount equal to the sum of the focal lengths the light is concentrated, and by gradually approaching each other they disperse the light by increasing amounts up to 45°. In Fig. 6 the upper figure shows the greatest dispersion and the under one the parallel transmission; the shutters of the signalling apparatus are seen in the dark spaces between the lenses.

When the projector is so small that a single shutter can be used for signalling, another kind of dispersion apparatus may be used, illustrated in Figs. 7 and 8. The two frames carry alternate concave and convex lenses; and when they are so placed that the concave comes opposite the convex lens, the frames act like plain glass; but when the converse is the case and concave comes opposite concave by means of a sideways

Hosted by Google

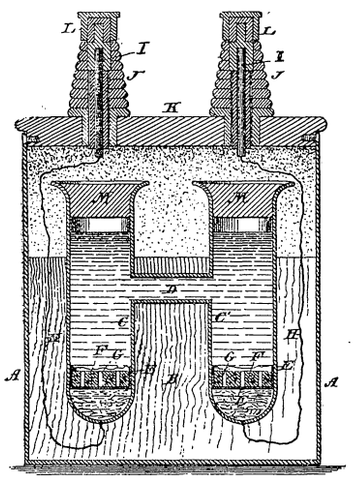
movement, then the dispersion caused by each frame is increased by the other.

A further improvement was added to these projectors by placing motors on their two axes in such a manner as to make them controllable from a distance, a device which is very useful on shipboard; and will continue to be of importance until the present single projectors are replaced by eight smaller ones arranged to illuminate the entire horizon, and this improvement can only be a question of time; only when this is accomplished will the projector have that importance in warfare which it is certainly destined to attain.

[Erratum.] On p. 713 of our last issue, the sentence beginning "the efficiency of a projector depends," should read on as follows:—(1.) On the size of the "useful angle"—that is, the angle contained by the rays which are *received* by the extreme edges of the *reflector or refractor*, this angle being a measure of the amount of the *light* which is *utilised* by the projector, etc., etc.

THE WESTON STANDARD CELL.*

Mr. Edward Weston's attention was early directed to the production of a primary standard of electromotive force. The standards of electromotive force available up to the present time did not come up to the ideal which Mr. Weston had set before him, even the best of these, the Clark cell, being subject to a variation of 0·077 per degree centigrade. In analysing the causes for this, Mr. Weston discerned that the density of the zinc sulphate solution



The Weston Standard Cell. Transverse Section.

is dependent upon the temperature of the solution, and with every change in density there is a corresponding change in electromotive force. Again, the local action which takes place in such cells affects the electromotive force to an appreciable extent.

Mr. Weston employs the cadmium salts. Their value for this purpose appears to be due to the fact that such salts are equally as soluble in hot as in cold water, the density of the solution remaining substantially the same, so that there is no disturbance of electromotive force due to changes in destiny. The chemical affinities in the cell are substantially the same, no matter what the temperature of the cell may be within reasonable limits. Any salt of cadmium may be used, the acid of which forms a practical insoluble compound with mercury when the salt is in the state of a saturated solution in water, or in a solution of the salt of cadmium employed. Such salts, for example, are the sulphate, the chloride, the bromide, and the iodide.

The cell may be made up in a number of ways, but one of the best arrangements for an absolute standard cell is to employ a saturated solution of cadmium salt in water, and as electrodes an amalgam of cadmium and mercury opposed to an electrode of pure mercury and proto-sulphate of mercury. The accompanying engraving shows the cell in transverse section. A is an outer shell of sheet brass and elliptical in form. In the bottom of this shell is inserted a wooden block B, containing cavities or recesses to receive the glass cells C C′. These cells consist of two cylindrical vessels connected by a transverse tube D. Within one vessel, C, there is placed an amalgam of cadmium and mercury, in the other vessel a mixture of pure mercury and proto-sulphate of mercury. There is then inserted in each vessel above the electrode a piece of muslin, E, the edges of which turn upward. In the cup-shaped piece of cloth thus introduced cork F, pierced with apertures G, is inserted. The arrangement of cork and muslin serves to hold the materials of the electrodes in place and prevent their becoming commingled with the solution when the cell is moved about. At the same time, the openings in the corks, F, allow of free contact of the solution with the electrodes. There is then placed in each cell, C C′, a saturated solution of cadmium sulphate. Lastly, the stoppers, M, are secured in place with cement. The connecting wires, H, pass through the bottom of the cells, C C′, and communicate electrically with the electrodes. They are connected to copper wires, I, which are received in binding posts, J. These binding posts, J, are carried by the cover, K, of the shell, which cover is made of rubber. The binding posts are provided with covering caps, L. After the cells are in place, the space in the shell above the block, B, is filled up with a composition composed of beeswax, resin, and linseed oil. The cover, K, is then adjusted and the cell permanently closed.

When the cell was submitted to temperature changes ranging over 200° F., Mr. Weston was unable to detect any greater variation of electromotive force than $\frac{1}{100}$th of 1 per cent. The electromotive force is 1·019 volt.

* Abstract from the *Electrical Engineer* of New York.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, April 28th.

PHYSICAL SOCIETY.

5 p.m. Paper to be discussed: (1) "Experiments on the Viscosity of Liquids," by Prof. J. Perry, J. Graham, and L. W. Heath. Paper to be read: (2) "On Luminous Discharges in Electrodeless Vacuum Tubes," by E. C. Rimington.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. Paper to be read: "Fire-Risks of Electric Lighting," by H. W. Handcock, Stud.Inst.C.E.

ROYAL INSTITUTION.

9 p.m. Evening Discourse. "Transmission of a Nervous Impulse," by Prof. F. Gotch, F.R.S.

SATURDAY, April 29th.

ROYAL INSTITUTION.

3 p.m. Tyndall Lecture (3): "Some Applications of Electricity to Chemistry," by James Swinburne, M.Inst.E.E.

MONDAY, May 1st.

ROYAL INSTITUTION.

5 p.m. Annual Meeting.

SOCIETY OF ENGINEERS.

7.30 p.m. Ordinary Meeting at the Town Hall, Westminster. Paper to be read: "Blake's Bridge, Reading," by Edmund Burrows.

TUESDAY, May 2nd.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read with a view to discussion: "Mining and Ore-Treatment at Broken Hill, New South Wales," by M. B. Jamieson, Assoc.M.Inst.C.E., and John Howell. At this Meeting, the monthly ballot for members will be taken.

WEDNESDAY, May 3rd.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Practical Electrical Problems at Chicago," by Prof. Silvanus P. Thompson, F.R.S.

THURSDAY, May 4th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Atmosphere," by Prof. Dewar, F.R.S.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Extra Meeting. First James Forrest Lecture: "The Inter-dependence of Abstract Science and Engineering," by Dr. William Anderson, F.R.S.

CHEMICAL SOCIETY.

8 p.m. Ordinary Meeting.

FRIDAY, May 5th.

CHEMICAL SOCIETY.

8 p.m. Hofmann Memorial Meeting: Addresses by Lord Playfair, F.R.S., Sir F. A. Abel, F.R.S., and Dr. W. H. Perkin, F.R.S.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Fogs, Clouds, and Lightning," by Shelford Bidwell, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Hosted by Google

The Electrician.

THE PROPOSED NEW UNIVERSITY FOR LONDON.

The latest scheme for the solution of the London University problem is that issued by "The Association for Promoting a Professorial University for London," which appeared in *The Times* of the 3rd ult. The scheme is a comprehensive one, and the difficulties which beset the path of the reformer of the existing institutions for higher education in London have been boldly faced, but whether they have been overcome is quite another matter.

It will be remembered that the Charter of the Gresham University was withdrawn from the House of Commons and referred to another Royal Commission still sitting; that Charter provided for a Federal University pure and simple. The University had no power whatever over the internal management of the affiliated colleges (except in fixing duration and nature of courses of study for degrees); it had no power to appoint professors, teachers, or lecturers, and in fact was no more entitled to the name University, in the true meaning of that term, than the existing University of London. It was merely a very cumbrous plan for giving every teacher some control over the examination of his students. The University proposed by the Association is the very opposite. Under their scheme every institution of University rank in London will go into the melting pot, and by the Medæa spells of a statutory commission, out of that pot will arise a glorious University full at once of the elasticity of youth and the vigour of manhood.

We propose to examine rather closely some of the details, and to point out what we fear are rocks ahead. In regard to the Preamble we have nothing but praise; it seems so often ignored that it is necessary again to reiterate what

Hosted by Google

ought to be self-evident—namely, that while the chief function, after all, of a University is to teach, it has an important responsibility in the advancement of science and learning by encouraging and endowing original workers and original research. That is to say, it should not confine itself to collegiate or other classes in which teaching should be the sole aim, but should afford opportunity for original investigations, and these should, in our opinion, be clearly distinguished from purely educational work. The proposed supreme governing body is to be the University Court, one half professors and the other half Crown nominees and elected members other than teachers. Since professors are likely to attend more regularly than the other members, this division seems likely to us to throw too much power into the hands of the professors—not a desirable thing. A very large share of the work of such a court is of a purely business character —financial, &c.—and will want very careful management, while it often enough happens that distinguished professors are far from being sound business men. Moreover, this preponderance of professors is a point of extreme importance in view of the fact that the appointment of all professors and teachers is to be vested in the Court, acting, however, on the recommendation of the Senate, a purely professorial body. The election, is therefore, likely to be entirely in the hands of the professors, which we do not consider an ideal state of things. The Court and the Senate will be such unwieldy bodies that the real power is likely to be in the hands of small executive Committees and Boards of Studies.

It is, however, in the change from the existing state of things that the main difficulty will occur; the proposal of a statutory Commission is an heroic measure, but we think it merely shifts the difficulty a step on and does not solve it. Is it the intention of the Association that existing institutions shall be forced into the scheme? If so, this is very drastic treatment and sure to raise a storm of opposition. Vested interests are usually very powerful, and have a way of asserting themselves in a way which often puts a stop to admirable paper reforms. Surely, too, some appeal from such a Commission should be granted. This was done with the Scotch University Commission dealing with far less knotty questions, whose ordinances all had to lie on the table of both Houses of Parliament before they became valid. Who are to be the members of the Commission? Are they to be entirely independent members, or drawn from the governing bodies of existing institutions. We fear there is great danger of such a Commission being overwhelmingly South Kensington in character, which would be a serious disaster. The names of the members of this Commission will have to appear before the proposed Charter becomes law, for on that Commission the whole future of the new University will hang. The labours of this Commission may make or mar the new University.

We must enter an emphatic protest against any idea to centralise the University, especially at South Kensington. It must not be forgotten that London is something more than a German University town, something more even than Berlin; it is a province in population, and almost in extent, and actually is if we include that Greater London which will be one of the main feeders of the University; it will not be residential, but students living all over London will attend in its lecture theatres and laboratories. It would most seriously cripple and injure the future of higher education in London were any idea of building a vast central block of buildings allowed to be carried out; the existing institutions and their buildings, on which hundreds of thousands have been spent, must be kept working as they are now, only with their appliances and staff strengthened. There is ample room for half-a-dozen professors or more in many subjects, and room for each to impress on his own students his own individuality. We have but little sympathy with so-called electrial *engineering* laboratories, and hold that the teaching of electrical and of mechanical *science* in lecture-rooms and laboratories should be separated from the training of an engineer in works and office. We pointed out on a former occasion that mechanics, mechanism, electricity and magnetism, and other subjects which form the foundation of engineering, fall under the well-established head of Physics. We should like to see these subjects treated scientifically, and not commercially, at the older Universities; but there appears to be a loud call for something called technical education, and on every side we find institutions at which the purely utilitarian parts are picked out and are taught to students who have no time for true science. We should like to see engineers receive their preliminary scientific education side by side with other men going in for other professions, and taking a more liberal view of the subjects than the mere commercial considerations demand. A little acquaintance with the spirit of true science would show the shallowness of the disparagement of "useless learning," and would prevent that wretched narrowness of mind which encourages men to think that there is nothing else worth thinking about in this world but their own profession. Applied science must be taught—at all events pure science having been studied, the proper method of applying it must be understood. It is this application which, being pushed too far, gives rise to laboratories side by side, the one for pure physics the other for men who, intending some day to join a profession in which a knowledge of physics is essential, are drafted off to learn a modified and "useful" edition of the subject. We credit a large number of professors at technical colleges with the best possible intentions, and our belief is confirmed by their repeated disclaimers of any desire to supersede future training in the workshop. We are, perhaps, fighting against the name electrical engineering laboratories rather than against the system; but we do so on the ground that parents send their sons to, and these sons pass through, such institutions, and naturally suppose that an electrical engineering laboratory is a place for learning electrical engineering. Having successfully passed through the course, they may be pardoned, then, if they fall into the error that they *have* learned electrical engineering. But granting, as we are very ready to do, the usefulness of such establishments to have, let us say, one electrical engineering laboratory for the whole of London would be harmful in the extreme; it would do much to arrest advance in higher technical education. It would lead to flooding the market with numbers of young engineers all cast in the one mould, and would tend to destroy individuality. We fear that to some extent there has been a failure on the part of the Association to recognise the just claims of applied science. It is too late in the day for any plan to be carried out which would be likely to drive the applied sciences outside the walls of the coming University of London. The engineering profession, in all its branches, is now-a-days deemed as worthy of University rank and recognition as any of the older learned professions, and while we cannot agree with this, for reasons which have been fully set forth in these columns in connection with engineering at Cambridge, it must, of course, under the circumstances be allowed to take its proper position in the Court and the Senate of the new University. May the Royal Commission show themselves worthy of the distinction assigned to them, and may we soon be able to welcome in the capital of the Empire a University worthy of the greatest city the world has ever seen!

REVIEWS.

Absolute Measurements in Electricity and Magnetism. Vol II., Parts 1 and 2. By ANDREW GRAY. (Macmillan and Co., London.)

This work, in conjunction with the first volume, already published, forms a book of reference of very great value. It is the most complete treatise yet written dealing with the theory and practice of electrical measurements. The writer has made full reference to the classical methods of treating the subject, and has also endeavoured with much success to bring the matter up to date. The result, of course, is a very lengthy book. The second volume consists of nearly nine hundred pages, mostly printed in small type, and it has rightly been judged advisable to bind the volume in two separate portions. Of these the first part deals with the more theoretical portions of the subject, and the second with the experimental methods of measurement. Throughout the book there are numerous references to experimental researches, but the work as a whole is distinctly mathematical, and the greater portion of it can only be read with advantage by those who have had the benefit of a mathematical training. The amount of time spent in selecting the analytical matter from the original Papers must have been very great indeed, and the author has in many cases put himself to the trouble of developing the mathematical expressions into a more practical form. Occasionally also the proofs given are original. In general, however, the mathematical parts of the book appear to be needlessly long. Frequently a long piece of analysis is given where a reference to the original Paper, together with the resulting formulæ, would have been quite sufficient. The student gains little by wading through proofs which involve the same principles over and over again, and the trained reader would be quite satisfied with the bare outline of the proof, if accompanied with the final result. This defect is noticeable in several places, but is specially marked in Chapter VIII., on the Measurement of Inductances. This chapter consists of no less than seventy pages devoted to describing the different methods of measuring the coefficients of self and mutual induction. Many methods are described, good, bad, and very bad; and, in each case, the appropriate formula is worked out at length. The proofs are all highly classical, involving the dissipative function and the equations of Lagrange. There is, however, no need to resort to such powerful analytical methods, since the results arrived at can be obtained much more simply, and it is unnecessary to give all the proofs in full, since the same method of analysis is employed in each case. It would have been far better to merely give the formula, and leave the student to work out the proof as an exercise.

The second part of the book is of more interest to practical electricians, as it deals with such subjects as galvanometry, the measurement of currents, the graduation of instruments by electrolysis, the graduation of voltmeters, the measurement of inductances, dimensions, the measurement of resistance, the comparison of units, the measurement of power in direct and alternating-current circuits, the measurement of strong fields, magnetic induction, hysteresis, and electromagnetic radiation. The chapter on galvanometers is well written, and contains much practical information. The latest form of d'Arsonval galvanometer, that of Messrs. Ayrton and Mather, is illustrated and described; but the great advantages of galvanometers of the d'Arsonval type are not sufficiently dwelt upon. Voltametry is treated very fully, the researches of Lord Rayleigh and Prof. T. Gray on silver and copper electrolysis are given, and the subject-matter is much the same as in the author's smaller treatise on absolute measurements. The work of the Board of Trade Standardising Committee in connection with the Clark cell was not finished early enough to be incorporated in the book; but this should be added when a new edition is called for.

The book naturally contains a great deal of matter which hitherto has only been obtainable in the publications of learned societies. For instance, a full abstract is given of Prof. Poynting's celebrated Paper on "The Transfer of Energy in the Electromagnetic Field." More than 40 pages are devoted to a description of Hertz researches, and the mathematical theory of the oscillator, as given by Hertz, is reproduced, this being, we believe, the first time it has been published in English, with the exception of the original translation by Dr. Lodge, which appeared in *Nature* in 1888, and a short notice in Preston's optics. Later work on electric oscillations, done by Trouton, Poincaré, Bjerknes, and others, is referred to, although only briefly. Dr. Lodge's important work on lightning discharges is dismissed in a couple of paragraphs. The length already reached by the book is, perhaps, the chief reason for such a brief reference; nevertheless, it gives the reader a very unfair impression of the relative importance of the work of Lodge and Hertz. Dr. Lodge not only established the existence of electric surgings under novel circumstances, but showed that they could be detected very simply by means of sparks. Hertz, in addition, made experiments which proved that these waves took time to travel through space.

The matter is brought well up to date. Ewing's magnetic curve-tracer is described, and the recent work of Hopkinson on hysteresis and transformer testing. Alternate current measurements are discussed very fully, and the results of some of the most recent tests of transformer efficiencies are given. The book has been written in the short intervals of time available from other duties, and the arrangement of the matter has, to some extent, suffered, but there can be no question as to the great value of the work.

Telephone Lines and their Properties. By W. J. HOPKINS, Professor of Physics, Drexel Institute, Philadelphia. (Longmans, Green, & Co.)

This is a good book, and into its 258 pages there is gathered a large amount of information, in fact, the propagation of telephonic electrical currents is treated with a grasp and completeness which will be beneficial in helping telephone engineers to appreciate and grapple with the difficult problems which confront them.

The book is, be it obsesved, descriptive of American practice, both as regards the erection of poles and wires and the employment of cables and conduits. There are brief chapters also on wire, insulators, exchanges, and switchboards, but valuable rather to the student than to the practical man, who would want to begin where these short summaries leave off. They are, however, well and clearly written, and will be useful to English and Continental readers as a sufficient guide to American methods, and they lead up very well, as they are intended to do, to the theoretical consideration of the subject which begins with Chapter VIII.

Professor Hopkins does not pretend to enunciate original views of his own, but taking the theories of Lord Kelvin, Lodge, Hertz, Maxwell, and other writers on the propagation of energy, and coupling them chiefly with the experimental researches of Mr. J. J. Carty of the Metropolitan Telephone Company of New York, he is enabled to present the theory of telephone working, with much clearness and lucidity. Indeed it is only within the last two years or so that materials for such a work have been available, and Professor Hopkins is to be congratulated on having so well put them into shape. We do not mean to say by this that the book is exhaustive in its treatment, or that it is a complete guide to any of the subjects with which it deals, but it does for telephony what in a great measure Dr. Fleming's late Paper has done for alternating currents as employed for electric lighting, that is, it levels up all round, puts existing knowledge on a firmer and clearer basis, and furnishes indications and suggestions as to how present methods may be improved and progress looked for in the future. The book is intended partly for students and partly for practical men, but it will be of most use to the latter, because there are few things in which practical experience is more desirable, in order to comprehend them properly, than telephonic disturbances and effects. They are so entirely abstract and incomprehensible until the ear has learned to distinguish and analyse them.

The author brings prominently into view, using chiefly as illustrations the experiments of Mr. J. J. Carty, the great influence of static effects in causing disturbances in telephone circuits as distinguished from the absorption and partial obliteration of electrical pulsations by capacity, with which the much-talked of $K = C R$ law deals. The experiments show

Hosted by Google

that where telephone lines run parallel, "cross talk" and some other disturbances are due to statical charge and discharge from neighbouring conductors, and to the tendency of charges so set up to dissipate themselves by forming currents along the conductor of the wire in which the induced effect is produced. They are not the result of simple dynamic action between wire and wire, as has been usually assumed to be the case, telephone currents being too small in themselves to produce this effect. The explanation, though not given in the book, seems to be that the transmitter induction coil in a set of telephone instruments sets up a current small in quantity but varying in potential, this potential reaching probably several volts. Owing to the great self-induction of the corresponding instruments at the other end of the line, the flow of the current is much retarded, and the whole line is brought nearly to the full potential which the first transmitting coil would produce on open circuit before much flow takes place, then the receiving set of instruments, that is to say, the phase of the current in the receiving instrument lags considerably behind the impressed E.M.F., and thus the line becomes charged to potentials which Ohm's law would never lead us to suspect. In this way much greater disturbance of surrounding dielectrics is produced than earlier writers suspected, and the extraordinary transference of articulate sounds from one circuit to another is satisfactorily accounted for.

Formulaire de l'Electricien. Par E. Hospitalier. Onzième année, 1893. (Paris: G. Masson.)

In external form and internal arrangement, this work retains the characteristics of the ten former editions. It is not a pocket-book—it is too large; it is not a textbook—its information is too didactic. Perhaps its most useful function is to be a work of reference on an office or a study table. There is much in the book that must be useful to anyone connected with electrical engineering, whether a professor or a practical man, and the material is well arranged. Perhaps it is a little hypercritical to express surprise at the information on page 362, that the current money of "Angleterre" includes a twopenny piece! The chapters on dynamos and motors have received some additions and have been brought up to date. We may particularly notice the data of the experiments on, and trials of, alternate-current motors at Frankfort and other places. The chapter on transformers and storage cells has also been extended. The old and very useful mathematical tables, especially that one which tabulates numbers and the two sets of logarithms on one page, still remain one of the best features of the book.

The Mining and General Telegraphic Code. By BEDFORD MCNEILL. (London: Whitehead, Morris & Co. 1893.)

In the compilation of this useful mining and general phrase code, the author claims to have endeavoured to include all the technical terms and sentences usually required by Mining, Metallurgical and Civil Engineers, and the Directors of Mining and Smelting Companies, with special regard for the needs of the financial departments. More than usual care has been taken in the selection of the code words, which, from a casual survey, appear less liable to telegraphic error than is frequently the case. In all, 44,572 phrases are included in the book, in addition to tables of numbers, moneys, measurements, weights and measures, &c. The code is frontispieced by a map showing the land and submarine cables of the world.

SOME APPLICATIONS OF ELECTRICITY TO CHEMISTRY.*—II.

BY JAMES SWINBURNE.

The electrolysis of fused salts has not been studied nearly so thoroughly, either from theoretical or practical points of view, as of the aqueous solutions of the same compounds. There are many reasons for this, the chief being the inconvenience of having to work at high temperatures. Though many of the salts appear to fuse easily, that is to say, at low temperatures, it will generally be found that they contain water of crystallisation in which they melt, and that the anhydrous salts need something approaching red heat. It is not easy to work with substances which are red or white hot. Again, many of the salts volatilise at temperatures close to their fusing points, and on the small scale necessary for laboratory work it is troublesome to regulate such temperatures with any accuracy. Nevertheless, the electrolysis of fused salts is of enormous importance. The production of caustic soda and bleaching powder by the electrolysis of a solution of salt has been discussed in the previous lecture; the electrolysis of fused salt is a much more tempting process. Chlorine is given off at one pole, and there is no trouble from formation of hypochlorites. At the other pole sodium comes off in vapour. Sodium, it need hardly be mentioned, is very much more valuable than caustic soda. It is largely employed for reducing aluminium from its chloride by substitution. In addition to that, however, it would provide a means of obtaining pure caustic, as all that has to be done is to allow water to act upon it. This would mean saving in packing and carriage. Many attempts have been made to produce sodium from fused common salt on a large scale, but, so far, the process does not seem to be satisfactory. Sodium is produced, but it is difficult to collect it well, as it comes off mixed with a great deal of vapour of salt. Then there is trouble with the anodes; any metal is attacked, as chlorine, of course, attacks a red-hot metal. Carbon also seems unable to stand. There is still another difficulty. Salt volatilises at a temperature not very much above its fusing point, and distils over with the sodium. In addition to this, hot sodium attacks silicates, so that it is difficult to collect it.

Common salt may be taken as typical, as its electrolysis shows most of the difficulties as well as most of the advantages of working with a fused electrolyte. In the first place, when a solution is used the electrolyte contains oxygen, and the result of this is that there is difficulty in reducing metals that have a strong affinity for oxygen—such, for instance, as sodium or aluminium. Water, of course, contains oxygen, and so does alcohol. Glycerine, which is a much more universal solvent than is generally known, also contains oxygen. Alcohol, which dissolves many metallic salts, such as nitrates, is unavailable for the same reason; and liquids like the hydro carbons, which contain no oxygen, do not dissolve salts, and are not conductors of electricity. If fused salts are employed, however, the difficulty is overcome. The various metallic chlorides are mostly easily fusible, and so are many fluorides and cyanides. By employing their fused chlorides, strontium, magnesium, calcium, aluminium and barium may be reduced electrically. Most chlorides can be prepared easily by dissolving the oxide in hydrochloric acid, and evaporating down. This process cannot be applied in the cases of barium, magnesium, or aluminium, as the metals have such an affinity for oxygen that hydrochloric acid is given off and the oxides, and not the chlorides, are left behind. There is an interesting point to be mentioned in connection with the electrolysis of fused sodium and potassium chloride; the yield of metal is said to be considerably below the theoretical value. It has been suggested that this is due to the formation of a sub-chloride. This suggestion is probably wrong; but it is worthy of careful investigation, as, if it is true, sodium and potassium cannot be monovalent metals. It has been suggested on quite other grounds that they are trivalent, which would, of course, make two more chlorides possible. Another curious phenomenon is that many fused salts appear as if they conducted without any decomposition—that is to say, they seem to act like metals. This also seems impossible. It would

* A course of three "Tyndall" lectures at the Royal Institution.

Hosted by Google

mean that fused electrolytes were an exception to the rule that all transparent liquids which conduct do so electrolytically. All transparent solids are, of course, non-conductors of electricity. It must be remembered that the distinction between fused and ordinary electrolytes is purely arbitrary, depending on the temperature at which we happen to live. If we were beings living at a temperature a few hundred degrees higher than the world is at present, we would regard water as gas and salt as a liquid, and Prof. Dewar would be freezing salt into the form they now know it, and liquefying water under great pressure. It seems unlikely that any extraordinary action, such as non-electrolytic conduction should take place in the case of a fused iodide; it is more probable that these salts are good solvents, and that the products of electrolysis dissolve and are carried over to the opposite electrodes. Potassium, sodium, lithium, strontium, magnesium, barium, calcium and aluminium can be easily reduced from their fused anhydrous haloid salt. Tungsten can be obtained from fused sodium tungstate and boron from melted borax.

It is remarkable that pentachloride of antimony and tetrachloride of tin, which are decomposed by water, are non-conductors. The mixture is also a non-conductor. The fused trichloride of antimony conducts much better if not quite anhydrous.

The chief industrial application of the electrolysis of fused salts is in the production of aluminium. One of the forms in which aluminium occurs in nature is a double fluoride of aluminium and sodium, cryolite. This ore is fairly plentiful, and was for a long time employed in Germany as a source of sodium in soda manufacture. The cryolite is fused and electrolysed in an iron vessel. This is kept hot, and the cryolite is kept in a molten state by the heat produced by the passage of an enormous current against the resistance of the electrolyte. Oxide of aluminium, or alumina, is in many cases dissolved in the cryolite also. Salt is frequently added to reduce the melting point, so that a lower temperature will serve. The electrical power is taken from large dynamos driven by water power.

It is not impossible that great things will come from fused salts in the future. One of the greatest problems of the age is to obtain power more economically from coal. The boiler and steam engine is not an economical arrangement, and many workers have tried to use carbons as the burning plate in a primary battery. Carbon has little affinity for oxygen at ordinary temperatures, but when it is hot it is possible to get a current with carbon as the positive element.

When an electrolyte is subjected to an electric current a transference of the radicles takes place, or, as it is generally put, there is a migration of the ions. If a solution of chloride of copper were electrolysed, and if there were no movement of the chlorine and copper during electrolysis, all the chlorine in the immediate neighbourhood of the anode would be used up and the water would be called upon to give up oxygen. At the cathodes, on the other hand, a little copper would be produced, but as soon as the salt in contact with the electrode was exhausted hydrogen would be evolved. The result would be that with, say, a 20 per cent. solution of the salt only a fifth of the chlorine and copper corresponding to the quantity of electricity passed would be produced, the rest being spent on decomposing the water. The solution would, in fact, be decomposed just in the proportions in which it came in contact with the electrodes. It is because the radicles change places and move in opposite directions that a continuous supply of chlorine and copper is produced. It is as if the chloride of copper were made up of molecules, each consisting of an atom of chlorine and an atom of copper; the atoms of chlorine and copper keep changing partners in such a way that the chlorine moves towards the anode, and the copper in the opposite direction. To use a homely simile, it is like the "ladies' chain," in which the ladies go in one direction and the men in the other, but they are nearly always in pairs all the same. This transference is made available in electrical tanning. It takes a long time to tan a thick hide, because the tanning solution penetrates the skin very slowly, because the cells of which it is built are impervious. Mechanical agitation will force the liquid into the interstices of the hide, but no farther; it cannot force the liquor through the walls of the cells. The passage of electricity, however, causes the tannin to pass through the walls of the cells also. It thus comes about that mechanical agitation alone does not accelerate tanning much, and electricity alone is also of little use, for the movement of the radicles is exceedingly slow. The combination is most effective, however, as the agitation brings the liquor into contact with the cells, and the electrical action drives it through the walls. The action of electrical tanning has been investigated by Dr. Rideal and Mr. Trotter, and it was during a discussion on a Paper of theirs that the lecturer suggested the explanation here given. Mr. Falkenstein is doing further work on the same very obscure, but interesting and important, subject. It has been proposed to utilise electric osmosis in various other ways, but so far without any important results. Experiments were made showing the reduction of sodium, calcium, antimony, tin and lithium from their fused chlorides. Fused glass was shown to be a conductor, and the local heating at the electrodes was shown.

THE DISTRIBUTION OF POWER BY ALTERNATE-CURRENT MOTORS.*

BY ALBION T. SNELL, MEMBER.

(*Concluded from page 720.*)

So far, if the difficulty of measuring the power be disregarded, the main point calling for improvement appears to be the magnetic pulsation. The mean variation does not, theoretically, exceed 7 per cent., and, practically, probably not 5 per cent. In order to still further decrease this, Dobrowolski has devised a very pretty combination of the open and closed type windings, which reduces the mean variation of the excitation to 3·5 per cent., when the magnetic field should be practically constant. The winding is shown diagrammatically in Fig. 11, and is known as the double-

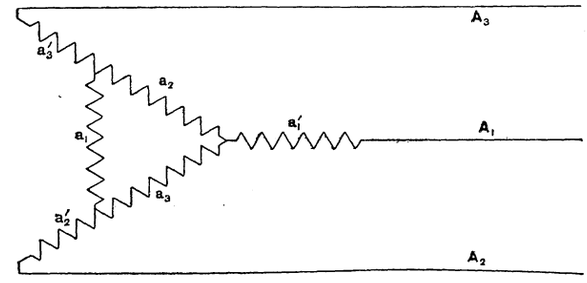

FIG. 11.—Combined *series* and *parallel* Drehstrom Couplings.

linked winding. The coils indicated by the symbols a_1^1, a_2^1, a_3^1, are severally wound in two parallels, 15deg. removed from the closed coils a_1, a_2, a_3. The complications involved are considerable, and the gain perhaps not commensurate with them; yet for large machines the device may prove useful.

There are some important points to be noticed between the *series* and *parallel* connections. It has been shown that with the *series* coupling $e = E/1{\cdot}732$ (*see* Fig. 8), and that the currents in the coils and mains are the same, and in the *parallel* device (*see* Fig. 5), that each coil carries a current equal to $A/1{\cdot}732$, and that the pressure at the coil terminals corresponds to the pressure between the mains. These differences are suggested by the terms *parallel* and *series*, which are in this respect more apt than those of *triangle* and *star*.

Now the magnetising effect exerted by a given number of turns of wire, and a definite effective current in the mains, will be different with the two kinds of windings. Consider Figs. 12 and 13, which severally represent the *parallel* and *series* couplings, and the direction of current at the instant when the Drehstrom is entering by one main and returning equally by the two others. Let n be the number of turns of wire in one coil. Then the total ampere-turns in the *parallel* device is n A, and in the *series* arrangement $3/2\ n$ A. Therefore, the magnetising effect and also the self-induction of the *series* device is greater than that of the *parallel* for a given current and a fixed number of turns. Now, the total power absorbed by the two circuits may be made the same by a proper adjustment of pressure and frequency; but since the lag is

* Paper read before the Institution of Electrical Engineers, April 13th.

Hosted by Google

involved, a complete solution is not very simple. Probably, however, a few experiments made with different-sized machines will do more to assist the constructor than pages of mathematical theory.

It must be borne in mind that the triphase system has not been definitely proved to be superior to the diphase, and the leading authorities on the subject differ strongly. Herr Dobrowolski says that "the diphase current now belongs to the past," because in practice machines give curves departing so widely from sine functions. He admits, however, that if the phase differences of current and pressure be the same in each of the two circuits and *follow a sine law*, the work is the same in each at the same instant. Messrs. Brown, Kelly, Stanley, and Kapp all maintain that there is little to choose between the two systems from this point of view; and Mr. Brown further states that "his extensive experience with multiphase currents shows that two or three-phase motors of similar outputs are much the same machines with regard to their respective efficiency, starting torque, weight, and apparent watt consumption. This holds good for synchronous as well as non-syncronous machines." It is generally admitted that the Drehstrom presents many difficulties for lighting, and still more for a combination of lighting and power work; but Continental engineers have to a large extent successfully overcome these. Whereas, on the contrary, the diphase system admits of as simple a treatment as the single-phase one. It appears to be, therefore, probable that, if multiphase currents come into general use, the diphase may be employed chiefly for combined *light and power distribution*; and that the Drehstrom may find its field of usefulness in *transmission* and *distribution of power*. Experience alone can settle these points.

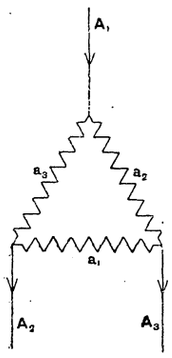

FIG. 12.

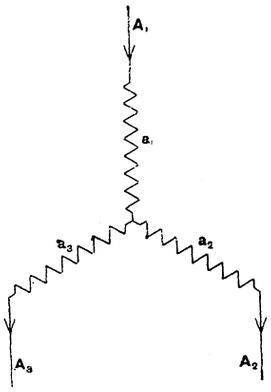

FIG. 13.

6.—*Practical Application of the Drehstrom.*

With a view of adding to the somewhat scanty practical information on the subject of multiphase working, the author proposes to lay before the Institution a few tests of two Drehstrom machines, designed and built by himself some eighteen months ago. These machines were adapted from material at hand, and were built under restrictions as to cost and time, and thus can only be regarded as rough experimental designs. The dynamo was a Gramme-wound 10-unit two-pole shunt machine, designed to give 160 volts and 60 amperes, at a speed of about 1,000 revolutions per minute. Three insulated copper rings, with suitable brushes, were fitted around the commutator and connected to the windings of the armature at points 120deg. apart. The ordinary commutator and brushes were left intact, so that both direct and triphase currents could be taken from the armature, and the field was separately excited. At a speed of 720 revolutions per minute, the frequency was 12 $\sim$ per second. This was afterwards increased to 33 $\sim$ by raising the speed of the armature.

The motor was specially built, and had a laminated ring magnet, with Gramme windings, and a closed-circuit armature. It was estimated to give 3 B.H.P. at about 1,200 revolutions per minute, and the gross weight was approximately 300lb. The armature plates had holes drilled parallel to the shaft and as near to the periphery as possible without breaking through. In these were placed lengths of No. 4 S.W.G. copper wire, insulated from the plates and soldered at either end to massive copper rings. The field winding consisted of six coils, each containing 68 turns of No. 6 S.W.G. copper wire, and having a resistance of 0·055 of an ohm. Opposite coils were joined in series with each other, so as to make three separate circuits, each of 136 turns and 0·11 of an ohm resistance, which could be connected in star or triangle fashion as desired. This motor proved to be a very effective machine, having considerable torque at starting, and a speed regulation quite as good as a direct-current machine of similar output. The only instruments available for taking electrical measurements were a Cardew voltmeter and a Siemens dynamometer; hence it was not possible to measure the angle of lag, or estimate the true watts. The experiments made with the dynamo and motor are shown in the following curves and tables, which at this stage may be instructive, since they show the order and direction of the difficulties met with in Drehstrom working.

(*a.*) *Preliminary Experiments with the Dynamo.*

The three copper rings were connected to points in the winding at 120deg. apart, the Gramme winding being otherwise untouched. The arrangement is diagrammatically represented by Fig. 14. The

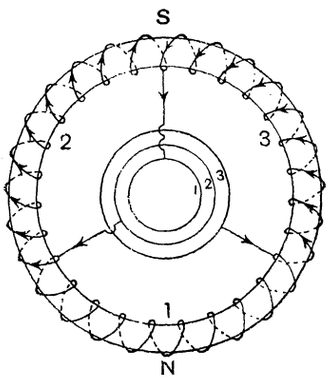

FIG. 14.—Connections of Drehstrom Dynamo, Coils in Series.

field was separately excited by 3·05 amperes, and the speed was kept at 710 revolutions per minute. The load was absorbed by iron spiral resistances with small self-induction. Readings were taken of the direct pressure; the alternating pressure at the ends of the three coils, a_1, a_2, a_3; and the current in each of the three mains, A_1, A_2, A_3 (*see* Fig. 15, curves 2 and 3). It was found that with the armature unloaded the pressure developed by each coil was practically the same; this was also the case when they were equally loaded (*see* Fig. 16). But it fell rapidly as the current increased, and

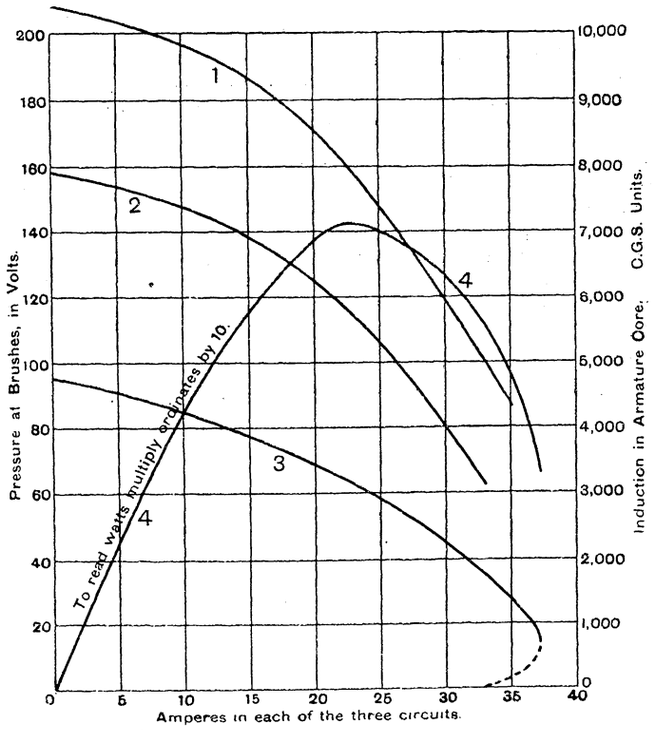

FIG. 15.—Curve 1. Induction in Armature Core. Curve 2. Direct Pressure. Curve 3. Alternating Pressure. Curve 4. Apparent Watts in each circuit. Speed 710 revolutions. Exciting current 3·05 amperes.

so a considerable difference could be made between the pressure of the three circuits by simply giving different loads to each of them. The magnetic induction of the armature core, curve 1, Fig. 15, was calculated from the usual formula, $E_a = N A n/10^8$, where E_a equals the total number of volts in the armature, A the number of turns counted all round the armature, N the total flux, and n the number of revolutions per second. It will be seen that the values of the induction measured were all small. The frequency was 12 per second. These conditions were not the most favourable, it is true,

Hosted by Google

but they showed the detrimental effects of internal resistance and self-induction in not only restricting the output, but also in affecting the regulation of the pressure of distribution. It will also be seen that the direct pressure is higher than that of the alternating in the proportion of 158 to 94 on open circuit; and with 20 amperes in each branch (or a total of $1{\cdot}732 \times 20 = 34{\cdot}64$ from the combined circuit) in the proportion of 124 to 70. This difference is to be expected, since the alternating pressure is the average value of 120 deg. of the differential curve of potential; and, further, when

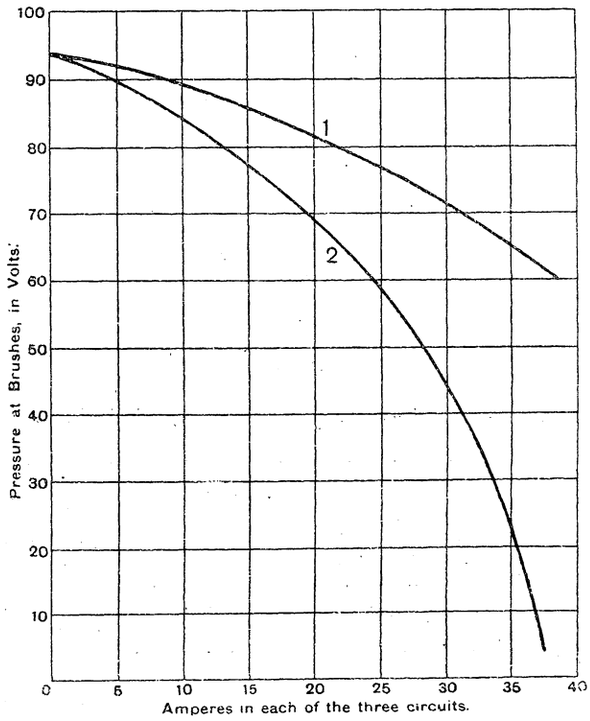

FIG. 16.—Shews Fall of Pressure at terminals of Drehstrom Dynamo with Armature Coils coupled as in Fig. 14. Curve 1. Only one circuit loaded. Curve 2. All three circuits equally loaded. Speed, 710 revolutions. Exciting current, 3·05 amperes.

the armature is loaded, the self-induction probably increases the difference between the two values. The apparent output, curve 4, Fig. 15, estimated by the product of effective amperes and volts is found to be a maximum with about 22·5 amperes in each circuit, or 39 in all. The current was next increased in each circuit so as to find the slope of the external characteristic curve. It was found to steadily fall at about the same slope until 37·5 amperes were reached, corresponding to a torque due to 65 amperes, this current being rather more than that designed for the armature. At this point the belt began to slip, and the experiment was stopped. It is clear that this class of dynamo can be safely overloaded for short periods.

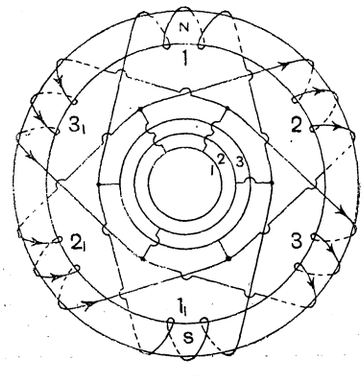

FIG. 17.—Connections of Drehstrom Dynamo, opposite Coils in Parallel.

The winding of the armature was next divided into six equal parts, and opposite sections were joined in parallel (*see* Fig. 17). The copper rings were then connected as before to points at 120deg. from each other. Each of the three circuits had now only half as many turns as with the coupling shown in Fig. 14, and one-fourth the resistance. The effect of this alteration was to lower the internal resistance of the armature and also, presumably, to reduce the self-induction. The excitation was maintained as before at 3·05 amperes, and the speed also at 710 revolutions. The results obtained from the two couplings are shown in Figs. 16 and 18 respectively. It is noticeable that the parallel winding has not materially affected the apparent output of the dynamo. The effective number of turns in each coil is only one-half that with the series winding; and, therefore, for the same heating effect the number of amperes is twice as great. To compare the two outputs, then, it is necessary with the series arrangement to take only half as many amperes as with the parallel one. Referring to Figs. 16 and 18, it is found that the apparent watts at 710 revolutions per minute are severally 69×20 and 34×40, or approximately the same. There was probably a smaller lag of current with the parallel than with the series connections. The smaller pressure and larger current were most suitable for testing the motor, and so

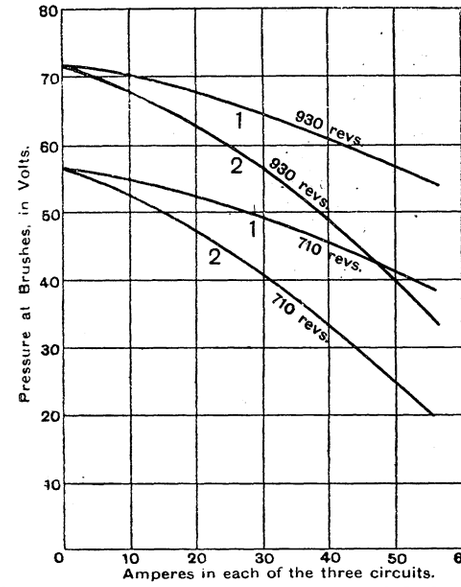

FIG. 18.—Shews Fall of Pressure at Terminals of Drehstrom Dynamo with Armature Coils coupled as in Fig. 17. Curves 1. Only one circuit loaded. Curves 2. All three circuits equally loaded. Exciting current, 3·05 amperes.

the parallel connections of the dynamo armature were used during the whole of the following experiments.

(*b.*) *Experiments with the Drehstrom Motor.*

(1.) *Star* or *open-coil* coupling. The motor was coupled to a dynamo by belting, and then supplied with current at frequencies ranging between 12 and 33·3 $\sim$ per second. With the lowest frequency the motor ran light at about 700 revolutions per minute, being nearly synchronous with the dynamo. As the load was applied the speed decreased, and since the output was inconveniently small, the dynamo speed was raised to about 900 revolutions per minute, when the following readings were taken :—

Groups A and B.

No. of test.	Speed of motor.	Pressure on Mains.	Amperes in each circuit.	Exciting current in dynamo field circuit.
1	848	58	21	2·5
2	746	55	21	2·8
3	880	77	38	4·5
4	800	77	27	Not taken.
1	888	80	28·7	4·3
2	866	80	27·6	4·3
3	824	75	27·6	4·3
4	890	77	28	3·9
5	790	70	27·6	3·9
6	866	75	27·6	3·9
7	Armature held stationary	70	34·7	3·9

The frequency was about 15 in the above experiments; but the dynamo speed varied from 932 to 833 revolutions per minute, owing to the engine governing badly.

The load on the engine was next adjusted so as to give a steady dynamo speed of 960 revolutions, and the tests included in Groups C, D, and E were made.

Hosted by Google

In C a prony brake was applied to the pulley of the motor, and in D and E a dynamo was driven, as in the tests of Groups A and B, this being found to be more convenient.

Group C.

No. of test.	Motor Speed.	Pressure on mains.	Amperes in each circuit.	Weight on end of 24″ brake arm.
1	736	84	31	2lbs.
2	624	82	32	3lbs.
3	500	83	32·9	4lbs.
4	500	81	33	4lbs.
5	340	84	34·7	5lbs.

The frequency was 16.

Groups D and E.

No. of test.	Motor speed.	Pressure on mains.	Amperes in each circuit.	Dynamo speed.
1	0	79	37·8	960
2	340	79	34·8	960
3	512	78	32·5	960
4	740	77·5	30·6	960
5	820	77·5	28·15	960
6	864	76	28·1	960
1	922	91	31	952
2	914	90	32·9	956
3	0	85	39·8	970

In both D and E the frequency was approximately 16.

Next, the dynamo speed was increased to 1,960 revolutions in Group F, and to 2,000 revolutions in Group G; and the motor connections were altered to the *triangle* or *closed type*. This required 1·732 times the current and 1/1·732 times the pressure for the same output with the *star* or *open type* (*see* latter part of 5). The prony brake was used in Group F.

Group F.

No. of test.	Motor speed.	Pressure n mains.	Amperes in each circuis.	Weight on 24″ brake arm.	B.H.P. of motor.
1	1,820	41·5	26·5	1	0·68
2	1,480	41	29·8	3	1·67
3	1,200	40·5	31	4	1·8

The frequency was 32·6.

Group G.

No. of test.	Motor speed.	Pressure on mains.	Amperes in each circuit.
1	0	36·5	39·4
2	732	37	35
3	1,000	37·75	35
4	1,276	38·75	30·5
5	1,702	41·5	27
6	1,750	42·5	27 Motor running free.

The frequency was 33·3.

Groups A and B were made to see how far the excitation of the dynamo affected the experiments. The pressure on the mains varies, of course, with the excitation, but the speed of the motor, as far as can be seen from these rough measurements, is nearly independent of the pressure, and seems rather to vary with the frequency and perhaps the lag. The law connecting speed and current variation for constant frequency and pressure of supply is not very obvious, and evidently requires the lag to be taken into account. For example, *see* Group B: in test 6 the motor loaded with 27·6 amperes in each circuit and 75 volts, makes 866 revolutions; and test 7 shows zero speed for 70 volts and 34·7 amperes. Evidently the lag in 7 is far greater than that in 6. This is confirmed by test 1 in Group D, by test 3 in Group E, and test 1 in Group G. It is curious to notice how small are the variations of current between running light and full load, or even when the armature is held stationary. This large waste or idle current is most prejudicial, and if it cannot be lessened by some practical means (by condensers or otherwise), will militate seriously against multiphase motors without commutators. If the revolving part of the motor be supplied with the triphase current, these troubles will be much less; because the moving part will contain less iron, and hence the hysteresis and eddy-current losses and the induction disturbances will be of less importance. The frequency in the induced circuit is then so small as to give little trouble.

In Group C a prony brake with a lever 2ft. long was fitted around a 6in. pulley, and the motor was supplied with current of 16 ∽ per second. The pressure and current variations are seen to be insignificant, though the speed varies some 50 per cent. This low frequency (16) was found unsuitable for the design of the motor, since it gave too low a speed; but the tests in Groups D and E were taken so as to show the capabilities of the motor under these conditions. The power of the motor was utilised to drive a direct-current dynamo, the two machines being coupled by a belt. The figures in Group D again show large variations of speed for nearly constant pressure and small changes of current. In Group E the pressure was increased, but only a few readings were taken, as the increase in speed was insufficient to give results widely different from those obtained in the preceding tests.

In the next experiments the connections of the motor were altered to the *triangle* or *closed* arrangement, the end in view being the increase of motor speed and consequence output.

The tests in Group F are some of the most important in the series, for the output measured by the prony brake was sufficiently large to give practical data. It will be seen that the frequency was 32·6 per second and the pressure about 41 volts. The speed again shows large variations. When running light the speed of synchronism, 1,960 revolutions, was nearly attained.

In Group G the motor was coupled to a small dynamo by a belt, and the frequency was raised to 33·3 per second. In test 6 the motor was running free, but the speed was 250 revolutions below that of synchronism. The best results seem to have been obtained with a frequency of about 32 (test 3, Group F), and it appears probable that if the arrangements had been such as to admit of a larger current at this frequency, at least 3 B.H.P. might have been taken from the motor.

These rough experiments show the importance of reducing the magnetising current to a minimum. It can be accomplished by careful attention to the design and by making the air-gap as small as possible. The Drehstrom motor may be regarded as an open magnetic circuit transformer, and the only way to lessen the waste current is to make the magnetic resistance as low as possible. Mr. C. E. Brown has already suggested bedding the field as well as the armature turns in iron, the method being applicable to either ring or drum windings.

7.—*Drehstrom Motors with Stationary Armatures.*

Triphase motors are sometimes made with the rotary magnetic field in the revolving part of the machine. This necessitates brushes and rings, it is true, and consequently simplicity of design is departed from; but it must be recollected that there can be no sparking under ordinary conditions. The brushes would probably be made of flexible strands of copper, such as are commonly used for alternators. The chief point gained is that the most marked effects of hysteresis, eddy-currents and self-induction are limited to the relatively small moving part of the machine; whilst the massive stationary portions, which then form the armature, are magnetised by currents of frequency equal only to the difference between the speed of the armature and that of the rotary field. It is clear that the speed of the revolving part can never equal that of the rotary field; but at normal loads the period of the armature current will be small, and therefore the heating from hysteresis, &c., will be comparable with that of a direct-current machine, the period being probably of the order of from 8 to 10 per second. Herr Dobrowolski's 2-H.P. motor described in *The Electrician*, August 7, 1891, is of this type, and a brief comparison with the small motor built by the author may be interesting, because it will show the order of the results obtainable from the two types of machines. Herr Dobrowolski's motor weighed approximately 565lb., and the maximum output deemed advisable was 4 B.H.P. at about 1,700 revolutions per minute. On open circuit it made 2,100 revolutions, and at 2 B.H.P., the rated output, about 1,950. The frequency was 35, the supply pressure 70 volts, and the torque at starting considerable. The lag was stated to be 72 deg. when the motor was running light, 28 deg. at 2 H.P., and 22 deg. at 3 H.P. The efficiency at 1 H.P. was 75 per cent., at 2 H.P., the rated output, it had reached to about 80 per cent., and at 2·3 H.P. it attained its maximum of 81·4 per cent. The author's motor weighed about 300lb., and at 1,200 revolutions gave 1·8 H.P. on the brake; and it was evident from the slight heating that this output could have been safely doubled if the speed had been raised to about 1,800 revolutions. But it had a larger lag than the other machine, the waste currents at small loads were much greater, and the all-round efficiency was certainly less.

8. *Combined Rotary and Synchronous Motors.*

A multiphase dynamo requires the revolving field magnets to be separately excited by a direct current. It is reversible and will run as a motor if supplied with a multiphase current, but is

Hosted by Google

not necessarily self-starting, and probably will not start against a large torque. If, however, the magnets be rotated so as to synchronise with the rotary magnetic field, the motor will work as satisfactorily as a single-phase machine. Attempts have been made to combine the advantages of a self-exciting rotary field and a synchronous motor. The plan proposed is some modification of the following idea:—The moving part, usually the armature, is wound with two circuits, the one closed on itself acting precisely as the closed circuits of the multiphase armature, the second supplied with a direct current, and, therefore, having fixed poles. When the field is excited by a rotary current the induced currents in the closed circuits will stert the armature (if the torque be not too great), and the permanent poles due to the direct current will have but little influence. But as the speed of synchronism is approached the induced currents in the armature will decrease, and the fixed poles will have more effect, until, finally, the armature rotation will be entirely due to them. Such a motor has many disadvantages, besides requiring an independent direct current. It necessarily has a low efficiency at starting and at all speeds below that of synchronism; but within wide limits of load, when once started, it will run at a constant speed with a high efficiency. The initial torque cannot be so great as that of a simple diphase or Drehstrom winding, since the closed circuits on which the starting depends are relatively smaller.

M. Schuckert has built a self-exciting diphase rotary-field synchronous motor on the above principles. But the method does not appear to offer any special advantages, and it is not likely that such motors will supersede ordinary single-phase alternators.

9.—*Single Phase Non-Synchronous Motors—Self-Exciting and Self-Starting.*

Messrs. Hutin and Leblanc, C. E. L. Brown, and others, have devised modified forms of Prof. Elihu Thomson's motor, all of which will run with single-phase currents, non-synchronously and with good efficiency. The principle seems to depend on the induction of currents in short-circuited coils, in unsymmetrical positions with reference to the main field, but this end is not necessarily attained by brushes and rings, as in Thomson's motor,* but by the rotation of the armature itself. In its simplest form this type of motor has no commutator, and is self-exciting, but will not start. If, however, the armature be spun in *either* direction, it will rapidly acquire the speed corresponding to the torque, and will then revolve at a uniform rate.

By the combination of an additional rotary magnetic field, the armature can be made to start against a considerable torque, and the auxiliary field can be stopped after the proper speed is attained. Various devices to secure such a field are suggested by Mr. C. E. L. Brown,† the most feasible being two parallel windings on the field magnets, one with small self-induction (or even capacity) and the other with larger self-induction. These two circuits when supplied with a single-phase current will produce a rotary field, and so cause the armature to revolve. (Other forms of this ingenious motor have been suggested by Mr. Brown, for which reference should be made to the technical journals of January and March of this year.) Most of the arrangements, however, necessitate rings and brushes, and the motor is, therefore, only preferable to a synchronous reversed dynamo inasmuch as it is self-exciting and self-starting. These two points are of great importance with small motors, and probably the invention will be of utility in many ways.

The general details of construction are, broadly, similar to those of a multiphase motor, but the number of poles in the field magnets and armature must not have a common factor, and the windings of both armature and field magnets are preferably laid in grooves or holes in the iron—an arrangement which permits the magnetic resistance to be reduced to a minimum and decreases losses from Foucault currents, while the weight output is increased. This is, perhaps, the best type of single-phase motor up to date, but it is undoubtedly susceptible of considerable improvement, and the problem of alternate-current motors suitable for running on ordinary supply circuits cannot yet be said to be satisfactorily solved.

The author has to thank several members, especially Prof. W. E. Ayrton and Dr. Sumpner, for kindly discussing with him some of the points raised in the Paper; but he alone is responsible for all inaccuracies and oversights.

DISCUSSION.

The PRESIDENT (Mr. W. H. Preece) said the subject of alternate-current motors was one of great interest at the present moment, and they were all looking forward to the introduction of an efficient one. He hoped the discussion on the Paper would lead to some novelty and some information.

Mr. KAPP, after referring to some things in the Paper which seemed to be printer's errors, proceeded to discuss the Paper. He must, he said, congratulate Mr. Snell for introducing it. English electrical engineers had been working with a cosine of lag that was really shocking. On the Continent and in America they had gone ahead at a great rate, but we had absolutely not a single multiphase current motor in practical work in this country. They might say that was because they were of no use; as a matter of fact that was not the case. There was quite a number of them doing excellent work abroad. There was no difficulty in a multiphase-current motor which would serve as an excuse for having neglected the subject so long. He would like to make a criticism which applied very much to most of the theories which had hitherto been put forth to explain multiphase-current working. Authors found it extremely convenient to neglect armature reaction. Now, if they wanted to investigate scientifically the theory of rotary field motors, at the same time leaving out armature reaction, it was very much like the proverbial case of playing *Hamlet* without the principal character. Armature reaction was extremely important, and it had not so small an effect as the author seemed to suppose. Mr. Snell had given them, though not quite endorsing it with his authority, the explanation of Dobrowolski as to why his three-phase currents were much better than the two phase currents, and why the complicated six-linked arrangement was better than the ordinary three-phase. Practical experience did not prove that at all. There was no disadvantage in the two-phase current. On paper, when they came to draw out those curves, it looked almost convincing; they saw those wavy lines going up and down, and they said, "It must be a very bad effect, having this pulsating field." But, as a matter of fact, they did not get that effect: it acted on an armature plentifully provided with good conductors, and the result of the presence of those conductors was that all the pulsations of the field were immediately wiped out. It was as though they had a transformer with a short-circuit secondary. When the secondary was short-circuited they could not get up any E.M.F., and that proved that they could not get up a pulsation of field; they could get up an E.M.F. which would burn out the transformer, but for a small pulsation they would not burn out the transformer. Any pulsation would immediately call forth opposite currents in the armature conductors which would balance the pulsations, and there was very little waste of power. That was, he believed, the only objection which the advocates of three-phase currents had been able to raise against the ordinary two-phase current. But, on the other hand, the ordinary two-phase current had the enormous advantage of being easily regulated. The three-phase current had been introduced in Heilbron, and it worked admirably there; but the superintendent had had a very heavy time of it before he was able to balance all his customers properly, so that all three branches were equally loaded. At last he succeeded, and everybody was satisfied, but none of those present would envy him his job. There was one more point he wished to draw attention to. The author said:—"Mr. C. E. Brown has already suggested bedding the field as well as the armature turns in iron, and the same end may be attained by perhaps a better way—*i.e.* by winding the field coils in drum fashion." He (Mr. Kapp) failed to see how the particular way of winding could affect the magnetic resistance between the surface of the field and that of the armature. He would ask the author whether that was not an oversight.

Mr. SNELL thought they were talking at cross purposes, chiefly on account of the definition of field and armature. He had stated in the beginning of his paper that he regarded as the armature that part of the machine which had the induced currents in it, and the field that which received the "Drehstrom" current. The case to which Mr. Kapp had referred was an oversight.

The PRESIDENT said that from the list he had before him it was evident a good many members wished to take part in the discussion, and no doubt they would be very glad to have the opportunity of clearing away a little of the fog that might have entered into their minds in consequence of the discrepancies in the paper. He knew that the motor that had been referred to was in London, and he was quite sure when he expressed the wish of the meeting to Mr. Sparks he would at the next occasion be kind enough to bring the novel motor of Mr. Brown to their meeting, and he was not sure that they would not be able to see it in action. He would therefore adjourn the discussion for a fortnight.

* See *The Electrician*, March 16, 1893.

† All of these have already been referred to in the first portion of this Paper.

CORRESPONDENCE.

CONCENTRIC WIRING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the statement in my letter of last week that the drop of volts in the outer conductor might be minimised by increasing the section of the outer conductor at the expense of the inner, I omitted to acknowledge that the originator of the idea is Mr. T. B. Murray, of Biggar, by whom it was suggested to me. I beg you will afford space to repair this omission. Thanking you in anticipation,—Yours, &c.,

56, George-square, Glasgow, April 26, 1893. SAM MAVOR.

[Owing to pressure on our space we have been compelled to hold over a very lengthy communication on this subject from Mr. Sydney F. Walker.—ED. *E.*]

Hosted by Google

EXHIBITS AT THE INSTITUTION OF CIVIL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Kindly allow us to correct a small inaccuracy in your note upon this subject. The 60-I.H.P. engine exhibited, which had been running up to 1 p.m. on the same afternoon, was the *works* engine here—*i.e.*, the engine which drives the machine tools, not the lighting engine. An exact representation of it chances to be given on the advertisement page exactly opposite to the "Note" in question, with the base and pulley, the two latter being the only portions not shown at the Institution.—Yours, &c., WILLANS AND ROBINSON (LIMITED),

Thames Ditton, April 25, 1893. C. S. ESSEX, Secretary.

EFFICIENCY OF TRANSMISSION.

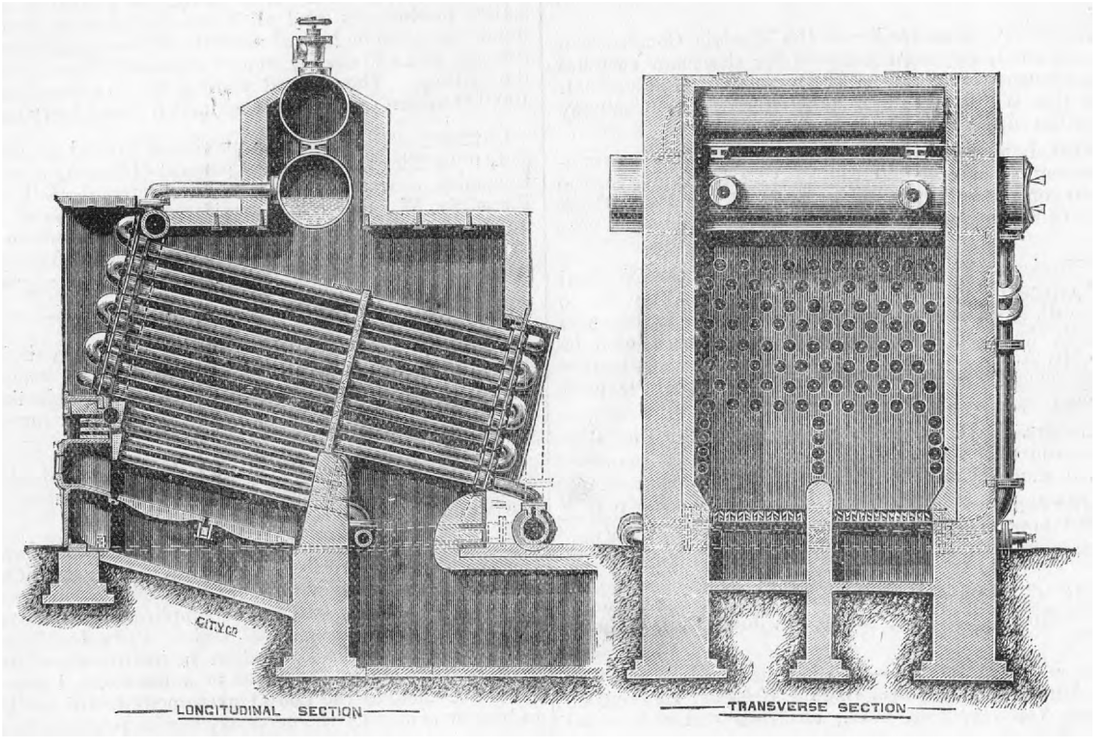
TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your summary—or note—on Mr. Preece's interesting lecture at Liverpool you say that his "expression of the efficiency of the transmission of energy by transport of coal is not only correct but original." Allow me, therefore, to point out that when the Planté cells or accumulator batteries were being puffed some years ago I ventured to criticise some statements by Sir W. Thomson concerning the transmission of energy by such storage cells, and to point out that an ordinary railway truck formed by far the more economical method of transmitting energy. My letter was, I think, published in *Engineering*. The efficiency of this method of transmitting energy depends, of course, upon the railway charges; but it is not fair to take the railway truck as the deciding example of such efficiency by coal transport, which varies greatly according to the means employed. For instance, coal is often carried many thousands of miles practically as ballast in the holds of sailing vessels. Again, its transport by canal is far less costly than by rail. In each of these cases the efficiency would be far less than any figures based on rail transport.—Yours, &c.,

J. T. BUCKNILL, Lieut.-Colonel.

ROOT'S PATENT WATER-TUBE STEAM BOILER.

Messrs. Conrad Knap and Co., makers of the improved Root boiler, recommend this tubular boiler for electric lighting purposes. the tube principle, whilst retaining the important feature of safety and facility for repairs, as well as ease of transport, which are



The accompanying illustrations show longitudinal and transverse sections of it. It will be noticed that the tubes are rather shorter than is usual in water-tube boilers, and it is claimed that a much higher rate of evaporation per square foot of heating surface is attained, together with greater facility in cleaning, and less danger of burning out when the boiler is forced. Each tube with its end boxes is separate. The tubes are screwed permanently into the end boxes, the difference of expansion being provided for in a bellows joint. We are informed that any tube can be replaced in ten minutes when the steam is down, and any leakage in the tube joints being external, can be seen and tightened up under steam. Instead of one steam drum, two small receivers are used, the lower one containing steam and water, the upper one steam only. No traps are, therefore, required, and it is claimed that perfectly dry steam is ensured. An interesting feature of this boiler is the surrounding of the furnace by 4in. tubes. These are clearly shown in the transverse section of the boiler. They are provided in order to absorb the heat which would otherwise be lost by radiation on to and through the brickwork. These tubes are set about seven-eighths of an inch apart, and about 1in. clear of the brickwork. Two rows can be provided if required, but we are informed that one is generally sufficient. This boiler is evidently a marked improvement over an "oven full of water pipes," maintaining, as it does, the leading characteristics of water-tube boilers. The tubular water casing is made entirely of wrought iron and steel, and is connected to the rest of the boiler in the same way as the other boiler tubes. It is not a separate water heater, but part of the boiler, and one in which the most rapid circulation of the water takes place.

Tower Lighting.—Tower lighting still continues to thrive in the land of its birth. Detroit, not content with having over one hundred of these strange structures, is agitating for more. As the American correspondent of a gas contemporary points out, the experiences of these tower-lamp trimmers during the past severe winter in the States must have been very trying. At Grand Rapids (Mich.) there are 40 tower lights. In ordinary weather the trimmer ascends in a kind of cage; but when there is a strong wind the cage rocks too much to make this plan safe. He is forced, therefore, to go up the ladder fixed on to the tower. Remembering that the towers are 150ft. high, it will be generally conceded that the task is one not to be sought after.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1893 Edition of "The Electrician" Electrical Trades' Directory and Handbook is now ready. This useful book contains over 1,000 pages, and several new and handy features have been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

Tenders Invited.—The Electric Lighting Committee of the County Borough of Huddersfield invite tenders for the wiring of and supply of electric light fittings for their supply station. Some particulars will be found in our advertisement columns, and Mr. A. B. Mountain, the borough electrical engineer, Gas Works-street, Huddersfield, will supply plans and specifications, and tenders have to be sent in to him by Tuesday, May 9th.

——— The Corporation of Cardiff require tenders for the erection of engine-house, boiler-house and coal stores, for the electric lighting station at Canton. All further information can be obtained of Mr. W. Harpur, Town Hall, Cardiff, and tenders must be sent in to Mr. J. L. Wheatley, Town Clerk, by May 6th.

——— The Corporation of Kingston-upon-Thames require tenders for the erection of the buildings for their lighting station, which have to be sent in to Mr. H. A. Winser, Town Clerk's office, by May 3rd.

Tenders Accepted.—The tender of the Electric Construction Corporation (Limited) has been accepted for the main switches and fuses for the electric lighting of the borough of Huddersfield, and that of the W. T. Henley's Telegraph Works Company (Limited), for the supply of cables.

Brockie-Pell Lamps.—Messrs. Johnson and Phillips have contracted for the supply of over 200 Brockie-Pell arc lamps for the electric lighting of the buildings and grounds of the Earl's Court Exhibition of Gardening and Forestry, which is to be opened next month.

Removal Notices.—The metropolitan offices of the National Telephone Company (Limited) will be removed from May 1st to 58-9 London-wall, E.C., and all communications and inquiries in connection with the Company's metropolitan business should be addressed to Mr. A. Calder, the metropolitan manager, at the new address. The general offices for other business remain at Oxford-court, Cannon-street.

——— Messrs. J. D. F. Andrews and Co. notify that they have removed the offices of the Company from 41, Parliament-street, S.W., to the works at Marsham-street, Westminster, S.W.

——— The registered offices of the St. James and Pall Mall Electric Light Company (Limited) will be transfered to their new central station at Carnaby-street, Golden-square, W., on and after May 1st.

——— Mr. G. Stegmann, electrical engineer, has removed from 66, St. John's-road, S.W., to 69, St. John's-hill, Clapham Junction, S.W.

Dissolution of Partnership.—The partnership between Vincent Sydney Allpress and Thomas Oswald Belshaw, carrying on business at 55, Victoria-street, S.W., electrical and mechanical engineers, has been dissolved.

Gilbert and Co.—Messrs. Gilbert and Co., of Hanway-street, and Kensington High-street, inform us that they are supplying electric-light plant for the Maharajah of Bhaunagar.

Messrs. R. and W. Winfield (Limited).—This firm has appointed Mr. Seymour Coneen, late manager to Messrs. F. W. Reynolds and Co., of Southwark, to the charge of their London business.

Personal.—Mr. C. Faraday Proctor, who has for some years past been associated with the Continental Edison Company, has now transferred his services to the Edison and Swan United Company's works at Ponder's End, where he will be specially concerned in the development of the fittings and instrument departments.

Hartmann and Braun's Electrical Governor.—Engineers in charge of central stations require a sensitive and trustworthy electrical governor. Such an instrument should control the station by acting on the exciting current of the dynamo, or, if batteries are used, on the switch which controls the number of cells in use. The essential part of such a piece of apparatus is an accurate standard voltmeter, which is specially sensitive between the limits of variation of pressure allowed. Messrs. Hartmann and Braun have adapted their new electrical governor to work under the conditions set out. It consists of a sensitive standard voltmeter which controls two relays, in their turn controlling the current of a small motor. The motor works a screw switch which alters the number of cells in use, or in a large station controls the dynamos by varying the existing current. The voltmeter has, therefore, only to deal with a very small current itself. At the ends of the switching screw are contacts placed which act on the motor circuits to prevent over running. Messrs. O. Berend and Co. are the agents in this country for Hartmann and Braun's instruments.

Automatic Electric Railway Signal Company.—An interesting working model of this Company's system of signals has been on view this week at 39, Victoria-street, Westminster. The working is entirely automatic, and may be briefly described as follows:—The train in passing depresses a spring rail, and makes contact with a relay. The relay makes and holds down a contact which pulls off a semaphore. A weight of two tons is required to depress the rail, which cannot easily be tampered with by hand, nor is it affected by platelayers' trolleys. The pull is comparatively small, as the semaphore arms are balanced. It appears that so long as they come to "danger" by gravity the Board of Trade do not specify any definite pull; but risk of sticking, due to snow, wind, or other causes, is guarded against by an ingenious device which prevents a further signal being lowered before the first one comes well home to "danger." Numerous contingencies are automatically provided for, and the invention, which has been at work for some time in the Isle of Wight, seems well worthy of the attention of railway men.

Exhibition at Antwerp.—An International Exhibition is to be inaugurated at Antwerp on May 5th, and is to remain open for six months at least. It is to include industrial, scientific, and artistic productions, and all kinds of commercial products. The buildings are to be located near the Scheldt, in the new quarter of the city, and will occupy an area of about 75 acres, connected with the railway. The general plan is for a covered area of about 100,000 square yards, including halls for machinery electricity, &c.

Concert.—The staff and a number of invited guests of the City of London Electric Lighting Company (Limited) were present at a Bohemian concert, held at the International Hall, Café Monico, Piccadilly, W., under the presidency of Mr. David Cook. This was the last of a series of four similar concerts, which have proved so popular that more than 300 persons assembled at the last of the series, including many ladies. This concert was a great success.

Acton.—A proposal which has been received by the Local Board, under which the Board would confer its powers for a limited period upon a firm of contractors who undertook to light the district for the same amount as is already paid, has been deferred for discussion by a special meeting.

Bombay.—The Bombay municipality has received a proposal from the executive engineer for lighting the Crawford markets and the Municipal offices by electricity.

Bournemouth.—The Local Government Board have written to the Town Council, notifying them that in the event of their intending themselves to generate or manufacture electricity for the purposes of lighting and power supplied, it will be necessary for them to obtain a Provisional Order. The Lighting Committee recommended that the Town Clerk be instructed to take the necessary steps to obtain the grant of a licence, and that application should be made to the Local Government Board for their sanction to borrow money for the necessary works, pending the grant of the licence. The Bournemouth and District Electric Lighting Company have been requested to furnish a tender, setting out the terms upon which they are prepared to light the pier and pleasure grounds, the Corporation providing the necessary lamps and fittings. The surveyor estimated the cost of the plant, &c., necessary for this work at £3,200. The Town Clerk anticipated no opposition from the Lighting Company to their application for a licence, as the light was only intended for the use of the Council.

Brighton.—Replying to a letter from a prominent ratepayer, the General Purposes Committee of the Corporation notify that, in the Bill before Parliament relating to the seashore electric railway, powers have been secured by the Corporation protecting their interests and those of the public. The borough surveyor has been instructed to report to the next meeting of the Corporation on the cost of lighting the Town Hall by electricity.

Bristol.—After submitting to the Town Council their report regarding the extended outlay for buildings and purchase of site for the central station, the Electrical Committee asked permission to withdraw a portion of the report until the next meeting of the Council, which was agreed to, the object being to submit a reduced estimate of cost.——The Board of Guardians have decided to light the main entrance of the hall, clerks' offices, &c., of the St. Peter's Hospital by electricity.

Hosted by Google

BURNLEY.—It was contemplated that the Burnley central station would have started the supply of electric current about the end of April, but, owing to a stoppage of building operations and a strike, it will be the beginning of June before a start can be made.

CHESTER.—The Electric Lighting Committee of the Town Council have before them two reports in reference to a scheme for lighting the City by electricity, and will shortly meet to discuss the matter.

CHISWICK.—The Local Board have received a letter from Messrs. Bourne and Grant, the contractors to whom the Provisional Order obtained by the Board was transferred, enclosing a memorandum and articles of agreement of the Company which is to be formed under the title of the Bourne and Grant Electric Supply Company (Limited) with a capital of £25,000. A proposal that Mr. Finnis should look into the matter and report to the Board was agreed to.

CITY OF LONDON.—The City of London Electric Lighting Company give notice of a further considerable extension of the area in which electric current will be shortly obtainable, the district including the area represented from Holborn in the W.C. district to Aldersgate-street, E.C.

DORKING.—The Dorking Gas Company have, we understand, under consideration a proposal to light the town by electricity.

FALMOUTH.—The Urban Sanitary Authority have decided to defer engaging an expert to report on the electric lighting scheme until tenders have been invited from public companies willing to light the town.

GLYNCEIRIOG.—This village has recently been provided with reservoirs for a new water supply, and it is under consideration to utilise the water for motive power in connection with a scheme for lighting the village by electricity.

GOUROCK.—The Town Commissioners have had under discussion the advisability of introducing the electric light into the burgh. There is some difficulty in obtaining a suitable site for an additional gas holder, and the introduction of electricity is, therefore, probable.

HAIPHONG.—We learn that the electric lighting of Haiphong is working successfully. There are four dynamos, made by Messrs. Mather and Platt, which at present supply 420 16-c.p. lamps. The 3-wire system of distribution has been adopted with overhead wires, the total length of the circuit being 17 kilometres. Two horizontal compound Marshall engines are employed, capable of working up to 12,000 16-c.p. lamps. The light is giving much satisfaction, and its extension is only a question of terms between the authorities and the Company working the district.

HUDDERSFIELD.—The borough electrical engineer of Huddersfield has been instructed to proceed with the laying down of another 200-unit plant, in extension of the present electric supply plant for the borough.

LAUNCESTON (TASMANIA).—Tenders will shortly be invited for the execution of the necessary works in connection with the scheme for lighting this city.

LECTURES.—Lectures on electrical subjects have been delivered during the week by Mr. W. H. Preece at Hampstead, by Prof. Fitzgerald at Belfast, by Mr. R. Hammond at Croydon, and by Mr. W. H. Watkinson at Sheffield.

MORECAMBE.—A difficulty which has recently arisen between the Local Board and the local Electric Light Company has been satisfactorily settled by the Company agreeing to conform to the orders of the Board in regard to the streets and footpaths being placed in a satisfactory state of repair.

POWDERHALL (EDINBURGH).—Tenders for the installation of electric light at the Refuse Disposal Works have to be sent in this day (Friday).

REDRUTH.—The formation of the Redruth Electric Lighting Company has had the effect of compelling the local gas company to reduce the price of gas by 6d. per 1,000ft.

TECHNICAL EDUCATION.—The Government of India have sanctioned the establishment of a technical school for engineering in connection with Rangoon College for training Burmans, and the Lieutenant-Governor of Bengal has sanctioned the opening of a technical school at Burdwan for the instruction of artizans. In Madras and other parts of India the establishment of technical schools is making considerable progress.

WATFORD.—A proposal that the Local Board should apply at once for a Provisional Order has been approved, and at the next meeting the Clerk will report upon the subject.

WHITEHAVEN.—Considerable progress is being made with the necessary works for carrying out the electric-lighting scheme. The first boiler has been fitted, and the engines and dynamos are expected immediately. August next is expected to see the central station in perfect working order.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

March 28, 1893.

6,556. H. H. LAKE. London. Improvements in electrical instruments for medical purposes. (Boyd's Medico-Electrical Vitalizer Company, United States).*

6,559. M. W. DEWEY. London. Improvements in electric heating apparatus.*

6,565. SIEMENS BROTHERS AND CO. (LIMITED) and E. F. A. OBACH. London An improvement in dry voltaic cells and in conducting connections for the carbons of these and other electric cells.*

6,573. F. BROWN. London. Improvements relating to voltmeters.*

6,579. W. MITCHELL. Improvement in electrically-heated radiator.*

March 29, 1893.

6,605. E. T. PARKER. Wolverhampton. Improvements in diaphra for use in electrolytic processes.

6,613. The Honourable C. A. PARSONS and J. B. WILLIS. Birmingham. Improvements in street and like boxes for containing transformers used in electrical distribution.

6,627. I. A. TIMMIS. London. Improvements in the working of railway signals and points by electricity.

6,637. F. W. GOLBY. London. Improvements in the application of electricity to closed carriages. (A. Casella, jun., France).

6,642. D. MATHER and J. KEMP-WELCH. London. Improvements in securing the socket shank of incandescent lamps.

6,649. G. A. NUSSBAUM. London. Improvements in telephone transmitters.

6,654. E. F. TERREY. London. An improvement in connection with electric bells and their contacts or current interruptors.

6,666. W. GEIPEL. London. Improvements in or relating to the distribution of electricity.

6,671. S. O. COWPER-COLES. London. Improvements relating to electro-metallurgy of zinc.

March 30, 1893.

6,677. W. GRIMES. London. Improvements in railway electrical signalling devices.

6,684. H. L. MÜLLER and W. ADKINS. Birmingham. Improvements in lighting and extinguishing attachments for electric and gas lamps.

6,697. W. DONALDSON. London. Improvements in the heating of gases by electricity.

6,702. K. KOCH. Manchester. Improvements in dynamo brushes.*

6,723. C. T. SNEDEKOR. London. Improvements in coatings or coverings for electric conductors.

6,742. J. D. F. ANDREWS. London. Improvements in electric arc lamps.

6,751. E. PLACET and J. BONNET. London. Improvements in the extraction of chromium by electrolysis.

6,780. V. C. DOUBLEDAY. London. Improvements in secondary batteries. (M. Sussmann, Germany.)

6,785. F. HALLOWS. London. Improvements in or connected with apparatus for feeding carbons in electric arc lamps.

April 1, 1893.

6,800. T. J. FLYNN. Liverpool. Improvements in or appertaining to electric-lighting apparatus or plant for railway trains, tramcars, or other like vehicles.

6,805. E. W. STREETER. London. A new shade for lamps or candles, especially suitable for incandescent electric lamps.*

6,813. F. BRYAN. London. Improvements in electric arc lamps.

6,814. C. R. G. SMITH and J. GORDON. Improvements in the deposition of copper or other metal on ordinary insulated conductors.

6,885. H. H. LAKE. London. Improvements relating to electric railways. (Michael Angelo Cattori, Italy).*

6,886. H. H. LAKE. London. Improvements relating to commutator switches for use in charging electric accumulators. (Carl Liebenow, Germany).

April 4, 1893.

6,907. R. H. BEST. Birmingham. Improvements connected with the apparatus for raising or lowering the centre lights of chandeliers or electroliers.

6,921. F. ROSATI. London. Magneto-electric generator with fixed armature.

6,922. W. MITCHELL. Birmingham. Devices for electrically heating crucibles and other articles.

6,933. THE AUTOMATIC ELECTRIC RAILWAY SIGNAL COMPANY (LIMITED) and E. BLAKEY. Improvements in or relating to the working of signals and locking of points electrically at railway junctions.

6,935. A. G. Brookes. London. Improvements in meters or apparatus for making measurement of electrical energy. (Herbert Clarence Wirt, United States).

6,952. W. Mitchell. London. Improvements in electrically-heated crucibles and holders therefor.*

6,954. A. J. Jarman. London. Improvements in the construction of primary elements for producing electrical currents by the moisture and heat of the human body or by separate excitation.

6,965. R. Urbanitzky and A. Fellner. London. Improvements in and relating to electric furnaces.

6,975. E. L. Berry and F. Harrison. London. Improvements in or connected with apparatus for periodically completing and interrupting electric circuits.

April 5, 1893.

7,005. R. F. Yorke. London. An improved electric accumulator plate,

7,020. J. A. Kingdon. London. Improvements in the construction of electro-magnets and in their application to electromotors and apparatus for use with alternating currents.

April 6, 1893.

7,069. A. E. Field. Southsea. A new method of fitting telephone instruments.

7,082. F. W. Kelley. London. Improvements in flexible brackets for electric lighting and other purposes.

7,085. O. E. Wheeler. London. Improved apparatus for producing intermittent electric flash-light signals or messages by the Morse or kindred codes.

7,101. F. H. Medhurst and W. J. Hope-Johnstone. London. Improvements in apparatus for use in connection with electrical transformers.

April 7, 1893.

7,190. A. G. New. London. Improvements in the manufacture of the magnetic parts of electrical apparatus.

7,192. J. Eaton-Shore. London. Improvements in guards for electric and other lamps.

7,194. G. Averley. London. Improvements in vehicles running on rails, applicable to electric traction and for other purposes, and adapted to pass around curves.

7,199. S. Hellebrandt. London. Improvements in portable electric lamp apparatus.

7,213. J. S. Raworth and T. O. Callender. London. Improvements in the manufacture of concentric electric conductors.

April 8, 1893.

7,246. H. Nehmer. London. Improvements in material for conveying electrical currents to the human body.

April 10, 1893.

7,297. W. J. Starkey and B. Starkey. Manchester. Improvements in and connected with secondary batteries, applicable also to primary electric batteries.

7,342. A. Bergtheil and R. A. Marples. London. An improved system of conductors for the distribution of electrical energy and in apparatus used therefor.

April 11, 1893.

7,358. J. Wood. Barrow-in-Furness. The gipsy telephone or electric mahatma.

7,387. W. P. Thompson. Liverpool. Improvements in or relating to machines for electrically-welding metals. (C. L. Coffin, United States.)

7,389. W. P. Thompson. Liverpool. Improvements in apparatus for electrically welding or working metals.

7,404. J. Long. London. Improvements in globes, shades, saucers, glasses, incandescent lamps, lanterns, and other appliances used for diffusing and increasing the light arising from electricity, gas, candles, mineral and other oils.

7,407. J. W. Jones. London. Improvements in electric meters.

7,423. W. H. Fahrney. London. Improved means for telegraphing.*

7,424. Addison, Goodyear, Waterhouse, and the Waterhouse Electrical Manufacturing Company (Limited). London. Improvements in electric arc lamps.

7,437. H. H. Leigh. London. An improved microphone (Charles Mildé, Son and Co. France).*

April 12, 1893.

7,470. P. Willis. London. Improvements relating to electric railways, tramways, and the like. (James B. Sheldon, George L. Van Beek and Daniel J. Murnane. United States).

7,471. E. R. Wilder. Manchester. Improvements in and connected with electric annunciators.*

7,488. J. A. Archer. London. Improvements in electric battery apparatus.

ELECTRIC LIGHT REGULATING SYNDICATE (LIMITED).—This Company was registered on April 25th with a capital of £1,000 in £1 shares, to carry into effect an agreement between Edward P. Davis and Adrian C. Collins and this Company; and to carry on the business of electrical and mechanical engineers, electricians, suppliers of electricity for the purposes of light, heat, and motive power, and manufacturers of and dealers in all electrical apparatus, plant, and machinery.

COMPANIES' MEETINGS & REPORTS.

The Metropolitan Electric Supply Company, Limited.

The sixth ordinary general meeting of the Metropolitan Electric Supply Company (Limited), was held on the 21st inst., under the presidency of Sir John Pender, G.C.M.G., M.P.,

The SECRETARY (Mr. E. Cunliffe-Owen, C.M.G.), having read the notice convening the meeting,

The CHAIRMAN said: Gentleman, I presume that you will take the report as read. I wish in the first place to direct your attention to a misprint in the accounts as sent out to you, which has been corrected in the copies placed in your hands to-day. In item 2 of the capital account you will see that the addition of the sums expended on buildings up to 1891 and during the past year, which has been made to appear as £127,439, should evidently be £133,429. The total of the capital account is not affected, and the misprint has no bearing on any other of the published accounts. I now come to the examination of the accounts which are in your hands, and which I hope are sufficiently explicit as showing the results of the previous year's working There are, however, some details to which I wish to direct your particular attention, in order that you may more fully realise the improvement in our position. The capital accounts, Nos. 1 and 3, contain little that is new. They show that the £50,000 debentures, about which we spoke last meeting, were duly issued, and now form part of the Company's capital; and I would state that they are almost entirely held by the shareholders, which is, I think, a very satisfactory position. You will observe that the capital expenditure of the year has been principally confined to, first, the completion of the Amberley Road Station at Paddington, with its plant and machinery, and, secondly, the extension of the underground mains, which now amount to upwards of 200 miles, and the provision of the transformers and meters necessary for the supply of our continually increasing customers. I may here remind you that the Amberley Road Station was not contemplated in our original estimates; and it is, indeed, owing to the comparatively recent addition of the Paddington district to our original areas that the debenture issue became necessary. I must not omit to refer to the item for management expenses, they have, as I explained on a former occasion, been divided between capital and revenue, on what the auditors consider to be a fair principle, having regard to the time and attention which have been required in settling and carrying out the various details of construction, the charge to capital being a decreasing one, so that when construction is practically completed, the revenue will have to bear the whole of these charges, which I have no doubt it will be perfectly well able to do. There is another item which I would explain, as it appears for the first time on the accounts. I refer to the heading "expenditure relating to compensation for damage and cost of properties acquired"—£3,311. 18s. This sum is in respect of one of the greatest difficulties we have had to encounter in the carrying out of our works. It has been impossible to lay down large quantities of machinery in thickly populated localities without provoking a certain number of complaints of vibration which may or may not have been justified; and in some cases, rather than incur litigation, we have been forced to acquire properties closely abutting on certain of our stations. As you all know, these complaints are very often greatly exaggerated, and when people in possession of land discover that they can get a little money by finding fault, you may depend upon it that they lose no opportunity of doing so. I have again to refer to this question later on; but I would mention here that we have never found any difficulty in letting such property as we have offered to tenants, and we are receiving a very fair rate of interest on our purchases; so we are under no loss by them. We now turn to the revenue account (No. 4), and the first and most gratifying point to be noticed is that while the income from sale of current has increased 35 per cent., the cost of production has only risen about 4 per cent. The coal bill is, of course, the great item of interest, and the Board are glad to find that their anticipations that the consumption of coal would not increase at all proportionally to income have been so fully verified. They believe that the improvement in this direction will become still greater as the business increases. You will notice in this account the introduction for the first time of a "depreciation fund." As I stated when addressing you last year, the Board are fully alive to the need of providing for the wear and tear of the Company's buildings and plant, more especially of such items as accumulators. It must, however, be borne in mind, that our buildings are quite new, that the machinery is only now really settling down into full working, and that every penny of expenditure incurred in keeping it in the perfect order necessary for successful working, has been charged directly to revenue. Our accumulators are few, and eventually, I believe, they will cease to be an item in our system. The Directors, therefore, consider that they have fairly met the necessity of the case by appropriating the sum of £4,000 to this purpose, leaving the amount to be increased year by year, as may seem most desirable and practicable. It would further be seen that the Board have commenced a most desirable writing off of the item of preliminary expenses, which has been reduced by the sum of £1,000, and will by future reductions be gradually extinguished. After making these appropriations there still remains a balance to credit of net profit of £11,558, and the Directors recommend the distribution of the sum of £9,980 as a dividend at the rate of 4s. per share, leaving a final balance to commence the net revenue account of 1893 of £1,578. I wish to draw particular attention to paragraph 6 of the Report, for in it we refer to the fulfilment of the anticipations I have more than once expressed to you as to the decrease of working expenses in

Hosted by Google

proportion to the increase of business. We look to this feature as the proof of the ultimate prosperity of the Company, and the more we can employ our machinery the more economically can we supply our current. Our chief difficulty at present consists of the character of our supply to the residential portion of our districts. Private consumers as a rule do not benefit us to the same extent as commercial consumers. The reason for this requires some little explanation. It will surprise many of you to know the varying requirements of householders, for whereas some consider that 10 lamps would meet their wants, others require many hundreds, and it is not always the largest houses that contain the greatest number of remunerative lamps. The effect of this on our supply is not altogether satisfactory. The small consumer who uses all his lamps regularly is a far better customer for us than the large householder, whose normal consumption bears an extremely small proportion to his maximum requirements. Once, twice, or three times in a year he will turn on all his lamps, and our machinery has to be prepared to meet this emergency, which may come at any time. It is also noticeable that this condition of affairs occurs mostly in the houses of those whose residence in London is of a limited and uncertain duration. We are therefore under the necessity of maintaining a certain portion of our machiney in reserve, which, under other conditions, might be more profitably employed. To show the great difference in the yield per lamp of our various classes of customers, I may state (as I feel that I cannot give you too much information on the subject) that restaurants and other establishments, whose business entails long burning hours, bring us sometimes as much as 30s. per lamp per year, whereas many private consumers only average about 2s. or even less In one or two extreme cases we only get a return of 4d. per lamp installed per annum. These are enormous differences, but I hope they will be rectified by-and-by in a way which will, I think, be perfectly fair between the Company and their customers. To meet these fluctuations and to benefit our good customers we have lately adopted a system of charging by sliding scale, which experience has shown to be well adapted for the purpose; but there is no doubt that the time is not far distant when an effort will have to be made to obtain a minimum return for every lamp which is connected to our mains. It must be understood that we do not keep our plant entirely idle to cope with possible maximum demands, which, of course, would never all arise at one and the same time. We have, therefore, the power of allowing an ample margin for taking on additional lamps, without any perceptible increase of working expenses, the cost (with the exception of a small additional amount of coal) having in any case to be incurred. Experience is teaching us how far we can safely increase our lamp connection beyond the number which our machinery is calculated to supply at one and the same time, and in the light of that experience we are able with confidence, to fill up our area more closely than was originally anticipated would have been possible with our present plant. With regard to the number of lamps connected, the diagram upon the wall will show you how regularly the increase has grown, and I may state that from the applications now in hand we have every hope that this steady demand will be maintained. We have a large number of applications, and they seem to keep steadily coming in. As far as I can see now, the position is this ; we have covered all our expenses, and we are in a position to pay a small dividend—a very small dividend, I am sorry to say—but a dividend that ought to improve every day. The question of street-lighting, to which I referred last year, is still in abeyance, but of course it is possible that we may be called upon by the local authorities to undertake this work. We have no intention, however, of entering into any contract for this purpose except at fairly remunerative terms. I may tell you that we declined to light the City on the terms that were offered, and we have no reason to regret having refused to take up that work. The new street which the London County Council propose to make from Holborn to the Strand would seriously affect our Sardinia-street station, and we have taken precautions to protect our interests in Parliament. I understand, however, that the London County Council do not intend this session to proceed with their Bill as far as this street is concerned. If that project had gone on and the County Council had taken our station, they must have taken it on such terms as would not have been a bad bargain for us ; but we should have had to find another site and provide another installation, and, therefore, for the moment, I am very much better pleased at their leaving us alone. Every day they leave us alone, judging from what I am putting before you to-day (which I am doing with the greatest confidence) we are becoming a more flourishing concern ; and, therefore, if they buy us two or three years hence, they must buy us at a bigger price than they would have to pay to-day. There is one matter to which I should like to refer, which is giving us great cause for anxiety, and that is the complaints which have arisen of vibration at one of our stations. I am unable to say very much on this subject, as an action is pending; but I may tell you that our engineer, acting with the approval of the best experts we have been able to consult, has devised a plan for putting an end to all possible ground of complaint, and we are sanguine that the result of the works now in progress will prove successful. Were I to explain to day what we are doing, it would probably not be as plain to you as I hope to be able to make it when I next address you. Our Paddington station, to which I have already referred, has recently been publicly inaugurated, and it has given great satisfaction by its regular and efficient working. I was present with several of the Directors at the opening of the station. We had with us the whole of the vestry, and I can only say that there were nothing but compliments paid us for the way the work was done, and the very satisfactory manner it is working. We are on very friendly relations with the vestry, and I think that that area, which is a very extensive one, possesses great possibilities for the future. In order to meet the payments due on account of this station and to provide for the mains laid up to the end of the year, it has been necessary to incur liabilities slightly in excess of our present capital. We have also further expenditure to provide for the mains that are yet to be laid, and it therefore becomes necessary for us to issue the remaining £50,000 debentures. We are anxious that the shareholders should again have the first opportunity of subscribing for the new issue, and a circular will therefore shortly be issued to you on the subject offering them to you *pro rata*. I can only say, as I have stated in the past, that I doubt if there is any better security to be found in London than the debentures of the Metropolitan Supply Company. I have put these remarks on paper with the greatest possible care. We desire that you should have the fullest possible information—all the information we possess. We think it creates a better feeling between shareholders and the Board if there is a perfect understanding and perfect confidence between them ; and I must now in a few further remarks give you some little further insight into our experience. I may tell you at once that electricity is comparatively in its infancy. We have experienced that in our telegraph system, but you know what an enormous area our telegraph system now covers, and what a great success it has been. When I and some of my friends sitting around me some years ago saw that electricity was "kicking about" very much in the City on paper, we thought that the time had come when we ought to establish a system of electric light that would be, at all events, honestly constructed and faithfully carried out. We took advantage of the very best information, and we have had no speculation in our system. We took up systems that had proved to be successful in producing the light and in giving a fair return on the investment. Since then we have been learning something, I may say, every day. When we first issued our prospectus we believed that we should get at least 25s., and probably more, per light. I believed that most confidently myself, and when Mr. Edison was over here and paid me a visit, he also believed it, and inspired me with the same conviction. We, however, said that we would take the modest figure of £1, but if we received £1 for every light we have upon our register to-day, I should be declaring to you a dividend of over 10 per cent. at the present time. That is with respect to the past. I believe the average of our lights to-day is not more than 10s. As I have told you, it goes from 4d. per annum up to 30s., but, as I stated, we hope to remedy this extreme fluctuation. We have now surmounted all our difficulties in knowing something of the cost. Having read, as I have done, all the reports and speeches that have been made in regard to electric lighting, I shall, I think, be prepared to show that we can produce the electric light as cheaply as, if not cheaper than, any of the other existing companies. You may on that naturally ask, Then why are you not paying a larger dividend ? The answer is that we have a much larger area to occupy. It will take us longer to fill it up, but when we have done so the case will be something like it was in the early days of gas—we shall be a growing and flourishing concern, and a much more extended concern than we should be if we occupied a very much smaller area, as is the case with some of the other concerns. In reading all these speeches, which I have carefully done, I have noticed that those who made them have pretty much the same idea as we have—that it is a matter of time. The electric light is likely to be the light of the future, and I think there are economies to be made which will go to the dividend side of the account. I have mentioned that we have laid 200 miles of mains. This means that we have drawn 200 miles of cable into conduits running under 85 miles of streets, at an average cost of £1,600 per street mile. We have laid a very large proportion, and provided for a very large increase in our lighting ; and, therefore, while we are not paying a large dividend to-day we are laying the foundations for paying a much larger dividend in the future. As I was coming into the room to-day I had a letter handed to me, in which the writer gave his ideas of the future of electricity. When we originally contemplated the formation of the Company we felt that electricity as a motive power was likely to be largely used. We still believe that that will take place, but we have had all our attention turned so far to introducing the light and completing our installations that we have not yet turned our attention in that way. The other day, however, I went to the opening of our station at Paddington, and found there Mr. Crompton, with all his beautiful appliances for cooking, using electricity for the purpose, and it was one of the prettiest things I have seen for a long time. This must take a very great hold not only in large but in small houses, and with our extended area I think we are likely to utilise our power for this purpose, and to utilise it at a time when it is not so much used for illumination, for all the motive power and a great deal of the cooking will be in the day time, whereas the electric light is used at night. I merely mention this, however, now. Promises and prophesies are not much until they are realised ; but, looking as I have done on many occasions, into the subject and studying the progress of electricity, and seeing the enormous changes that are taking place in our telegraph system, I think I am justified in calling your attention to these subjects as I am doing. We are now carrying four messages over a line at the same time—in other words, quadrupling the value of land lines and doubling the value of submarine lines. That has all been done in the past few years, and I think that similar changes will take place in our system. I think that those who are now shareholders in the Company, if they will hold on and be satisfied with a growing dividend, will find that they have not only one of the safest but also one of the most encouraging and steadily increasing investments existing at the present moment. We have recently received a letter from a customer who writes that he has carefully considered in connection with cooking the cost of electricity as against the cost of gas, and he says that electricity costs him only 25 per cent. more than gas. If electricity can be produced on a very large scale, and at a cost only 25 per cent. more than gas, I think that most people will go in for electricity. This gentleman adds that he has an electric silver grill, upon which he has his rumpsteaks done, and he finds them much nicer and more juicy than those done by the old frying pan. There is one feature about the electric light on which I will give you just an illustration in my own case. I have the electric light ; I do not get it from this Company, but from the Westminster Company—that is to say, I get it from the com-

Hosted by Google

pany that can supply me, and very well they do it. It is a beautiful light, and everything about it is very nice, but the difficulty, so far as the use of it is concerned, is to get the servants to believe that they ought to turn it off when it is not wanted. I have sometimes to take a turn round my house to see that this is done. I never leave my own room without turning off the light. The time was when the gas was allowed to burn in the same way, and to spoil the atmosphere in the house; but all that is now removed, and your lungs, your pictures, and your other property are immensely benefited by the use of the electric light. I am afraid I am detaining you, but I am very anxious that you should have as much information as I can give to you. We see now, in looking into our accounts, many ways whereby economies will be effected. We Directors have set the example by reducing our own honorarium by 25 per cent., but we do not want you to understand that cheap Directors are the best Directors, because men who can occupy the position that I am occupying to-day are not going to throw away their time and waste their lives merely for the purpose of being either abused or complimented by gentlemen who think that we ought to work for nothing. We shall work well for you; if we do not, turn us out. If, however, we work well and give you a decent dividend, and establish a strong and sound Company, we are entitled to be fairly considered. As I have said, in this respect we have set an example. We have also been anxious to introduce the very best element of work on to our Board. After careful thought we asked my friend, Sir Eyre Shaw, to join the Board. He has had great experience throughout London in connection with the Fire Brigade, which he brought to a state of perfection which probably no other country has been able to show in connection with such a matter. We offered him a seat at our Board, which he accepted after going round and examining the whole of our stations for himself. He can tell very well whether they are right or wrong in a few minutes with his experience. There is another matter which I must mention. In the midst of brightness there are dark shadows sometimes. We have had names associated with us which are not now occupying a very high position, and which have lately been mentioned, and not favourably, in the courts of law. When we first took up this concern we took over an installation called Whitehall Station. That was owned by a combination in which Mr. Jabez Balfour, Mr. Wright, Mr. Hobbs, and others were concerned in connection with the building of that immense place called Whitehall Court. On paper it looked an uncommonly satisfactory venture, and it must eventually be satisfactory to us when the whole of that place is lighted; but, unfornately, they thought that the place was to be filled up in a day, and many of us probably thought the same, but the result was that the light was not taken up to the extent that was imagined. We took this place over at a valuation which was made by Sir Frederick Bramwell and Sir Whittaker Ellis, and what we got was good value. Two of the gentlemen I have mentioned attended our Board for a short time, but only for a very short time, their attention being all the while taken up in other directions. At the time I am speaking of, Mr. Balfour was a very popular member of Parliament, and was very much employed by the Radical section of the Liberals in going about the country and making speeches. He was before the public very much, and was known as a public man, and I must admit that I did not inquire much beyond this. As a prominent Radical member, when the present Government was formed, I believe that Mr. Balfour applied for Cabinet rank. That was the idea of the man in the public mind at that particular time. Some people have told me that they knew better, but I did not. I saw him as a public man, and knew him as a member of Parliament, and I thought he was what you would call one of those men who was making honourable mark for himself. I have been mistaken, but I may tell you that when these two gentlemen were with us they had no special influence with us, and we have suffered nothing in any shape or form by them, while we are as clear of them to-day as is this sheet of paper. It is rather a painful thing for me to make this statement, but I thought it only right to you to do so. I only speak of these men as I knew them; I do not speak of them as they have since placed themselves before the pubiic. I think I have now pretty well exhausted all the subjects which I have to bring before you excepting one. We received a letter in reference to the accounts from a gentleman the other day—a Mr. Bolton. That gentleman went to the office of the Company, and every gentleman who chooses to go there will get every possible information that he can wish for, with certain exceptions. There are certain details which, if mentioned and given away in writing, would not be politic or just to the shareholders generally. Mr. Bolton called and asked whether the questions which he asked could be answered, to obviate the necessity for him to take up the time of the general meeting. We have no secrets; we will give every shareholder the fullest information which he is properly entitled to. I therefore instructed the secretary to write the following letter to him, and I think you will agree with me that it was a proper letter:—"Referring to your interview with me this morning, when you asked me to see the Chairman respecting your letter of the 17th inst., I am directed by Sir John Pender to say that he would prefer replying to the questions you ask in your letter at the general meeting, where all the shareholders will have an opportunity of hearing him. If you will, therefore, kindly attend the meeting to-morrow and put these questions, a full reply shall be made to them." The letter, I think, you will approve of. I do not say that it was so, but I thought that his remarks to the secretary implied his opinion that there was something wrong in connection with his questions, and that we were afraid to answer them. It seemed to be a kind of threat, and I will not occupy this position, and be threatened by any shareholder in this or any other place, although I will endeavour to satisfy every shareholder. I wished to state this to you, and to assure you that we stand before you to-day entirely free from any question in connection with the preparation of our accounts. Years ago, when I took a prominent part in establishing the telegraph system, I laid down the rule that our accounts were to be kept by a chartered accountant. All our accounts are in the hands of Messrs. Deloitte, Dever, Griffiths, and Co., and Mr. Griffiths is present to-day. They look after these accounts from month to month, and when the proper time comes they bring the accounts before the Directors. The Directors do not place the accounts before them. Probably Mr. Bolton is present, and if he wants to put any questions we shall be very glad to answer them.

Mr. BOLTON regretted that the Chairman had thought it necessary to say that an apparent threat had been made. All that he had asked was whether the secretary would be good enough to tell him how the item in the accounts of £4,787 was made up. The secretary, however, stated that he could not give the information without the authority of the Board.

The CHAIRMAN: Did you not ask to see the cash book?

Mr. BOLTON: Yes, under a misapprehension.

The CHAIRMAN replied that they had no intention of withholding information. He thought there was not much between them after all. He (the Chairman), however, preferred that the questions should be answered by Mr. Griffiths, whose firm had to pass the items.

Mr. GRIFFITHS said he had much pleasure in giving the information regarding the question of Mr. Bolton as to how the £4,787 was made up. Directors' fees, including that of the Managing Director, was £2,274; head office salaries, £953; printing and stationery, £246; postage and telegrams, £52; travelling expenses, £90; head office expenses, £52; office rent, rates, and taxes, £598; insurance and general expenses, including the debenture stamps, expenses of the Electrical Association and other things, £521.

The CHAIRMAN: Is there any other question?

Mr. BOLTON: I am perfectly satisfied with the answer of the auditor.

A brief discussion ensued, after which the report and accounts were adopted. The retiring Directors and auditors were re-elected, and a cordial vote of thanks to the Chairman and Directors brought the meeting to a close.

West Coast of America Telegraph Company (Limited).

The following report of the Directors of this Company will be presented to the shareholders at the meeting to be held at Winchester House, E.C., on Tuesday, May 2nd, at one o'clock:—

Pending the construction of the land line between Buenos Ayres and Valparaiso—which is being pushed forward as speedily as possible by the Pacific and European Telegraph Company (Limited)—no improvement in the traffic receipts was to be expected, the business of the Company being meanwhile virtually restricted to local messages. The completion of the new line will, however, re-open a direct service between the Company's stations and Europe, *vid* Lisbon, and thus enable the Company once more to handle European traffic at all its stations.

The gross income for the year 1892, as shown in the accounts annexed to the report, was £22,218. 16s. 9d., against £35,624. 16s. 5d in 1891, and in order to continue meeting the debenture coupons with regularity, it was necessary this year to take £10,287. 8s. 2d. from the reserve. The receipts include the sum of £4,782. 13s. 6d. from the Chilian Government in settlement of the Company's claim for damage to the cables during the revolution in 1891. The total expenses were £21,919. 14s. 8d., against £24,406. 19s. 7d. in 1891, showing that a real economy has been effected under this heading.

A concession has been obtained from the Chilian Government for an extension of the Company's cable to Talcahuano, with a land line to the city of Concepcion. The rising importance of this city, which is the centre of trade for the south of Chile, holds out a prospect of a considerable increase of traffic, both locally and by means of the new line to the east coast and Europe. The new cable was shipped for Talcahuano in February.

Mr. J. Denison Pender and Mr. Frederick Walters are the Directors retiring by rotation; both are eligible, and offer themselves for re-election. The auditor, Mr. John Francis Clarke, also retires, and is eligible for re-election.

Submarine Cables Trust.

The following report of the Trustees will be presented at the twenty-second ordinary annual meeting of the certificate holders, to be held at the offices of the Trust, 50, Old Broad-street, E.C., on Thursday, May 4th, at 12:45 p.m.

The revenue for the financial year to April 15, 1893, including the balance of £159. 13s. 3d. brought forward, amounted to £23,261. 13s. 11d. During the past year the following coupons have been met:—

Due.	Paid.
April 15, 1892	£1. 17s. 6d. balance August 2, 1892.
October 15, 1892	£1. 10s. on account October 15, 1892. £1. 10s. balance February 7, 1893.
April 15, 1893	£1. 10s. payable April 15, 1893.

The expenses of the Trust amounted to £1,627. 13s. 2d., and the payments on account of the coupons to £21,553. 17s. 6d., together £23,181. 10s. 8d., leaving a balance of £80. 5s. 3d. to be carried forward.

The table showing the original and present investments of the Trust, which accompanies the Trustees' report, remains unchanged from last year.

It is with regret the Trustees have to record the death of their secretary, Mr. William Payton. They have appointed as his successor Mr. A. Brodrick. The meeting will have to elect two auditors for the current year, and Mr. John G. Griffiths and Mr. John Gane offer themselves for re-election.

Hosted by Google

Brazilian Submarine Telegraph Company (Limited).

The following is the report of the Directors for the half-year ended December 31, 1892, to be submitted to the thirty-ninth ordinary general to be held at Winchester House, Old Broad-street, E.C., on May 3rd, at 12 noon :—

The revenue for the half-year ended December 31, 1892, amounted to £113,891. 15s. 8d., and the working expenses to £24,536. 6s. 6d. After providing £12,880 for debenture interest and sinking funds, and £1,547. 19s. 6d. for income tax, there remains a balance of £74,927. 9s. 8d.; to this is added £3,073. 8s. 5d. brought forward from June 30th last, making a total of £78,000. 18s. 1d. First and second interim dividends amounting to £39,000 have been paid and £35,000 transferred to the reserve fund, leaving the sum of £4,000. 18s. 1d. to be carried to the next account. The receipts for the half-year include the sum of £1,500 dividend to June 30, 1892, on the Company's shares in the African Direct Telegraph Company (Limited).

In accordance with the provisions for repayment of the first issue of debentures, dated July 31, 1884, 177 bonds, representing £17,700, were drawn on the 17th inst., for payment at par on July 31st next. This, with the previous drawings, will make a total repayment of £131,300, leaving £18,700 of the first issue of debentures outstanding.

In view of existing competition, the Directors have found it advisable to make a further reduction in the rates to and from South America.

During the last six months, several repairs have been successfully carried out; but, in consequence of the duplication of the Company's cables, the traffic was not interrupted. Arrangements have been made whereby the duplex system referred to in the report for the general meeting of May 4, 1892, can now be applied to either of the Company's cables. The land line from Buenos Ayres to Valparaiso to connect the west coast of America cable with the east coast cables, referred to by the Chairman at the general meeting held October 19th last, is being erected with all possible speed, and the Directors anticipate the line will be opened for traffic in about three months.

The principle of establishing staff pension and superannuation funds has been carefully considered by your Directors, who have had the details worked out by experienced actuaries, and a scheme will be submitted to the meeting for dealing with the matter, together with a formal resolution empowering the Directors to carry out the necessary arrangements.

The various sections of the Company's line are in good working order.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

BAILY AND GRUNDY, LONDON (LIMITED).—This Company was registered on April 24, 1893, with a capital of £10,000 in £10 shares, to take over the business now carried on by Robert M. Baily, at Amberley Works, London, W., and to carry on the business of electricians, mechanical and electrical engineers and contractors, suppliers of electricity, workers and dealers in electricity, and manufacturers of and dealers in all and any apparatus and things connected with the generation, accumulation, supply, distribution, and employment of electricity. The subscribers are :—

	Shares.
Robert M. Baily, Amberley Works, Paddington, W., engineer	1
Alfred Grundy, 32, Brassey-square, S.W., electrician	1
Edward Nathan, 168, Alexandra-road, London	1
George A. Knight, 4, Donaldson-road, Kilburn, N.W., engineer	1
Chas. S. Winbush, 72, Oakhurst-grove, East Dulwich	1
Fredk. A. A. Simons, Nilgiri House, Camberwell, engineer	1
Sydney B. Tatham, 16, Davies-street, Berkeley-square, W., electrical engineer	1

MERVEILLEUSE ELECTRIC ARC LAMP SYNDICATE (LIMITED).—This Company was registered on April 24, 1893, with a capital of £15,000, in £1 shares, to adopt an agreement made between Emilio Zuccani and Alfred Conder for the purchase of the patent rights of the "Merveilleuse Electric arc lamp" for the United Kingdom and Ireland, and to carry on in Great Britain and Ireland the business of electricians, electrical and mechanical engineers, contractors, and manufacturers of and dealers in electric arc lamps and other electric appliances.

PNEUMATIC WHEEL COMPANY (LIMITED).—Capital, £85,000 in £1 shares. Included among the objects of this Company is that of carrying on the business of mechanical and electrical engineers, india-rubber manufacturers and merchants, &c., and also of adopting an agreement to be made between George Philip (on behalf of this Company) and the Electrical Power Storage Company (Limited).

R. BOLTON AND CO. (LIMITED).—This Company was registered on April 22, 1893, with a capital of £12,000 in £5 shares, to enter into and carry into effect an agreement to be made between Reginald Bolton, A.M.I.C.E., and Herbert Coward (on behalf of the Company), for the acquisition of the business of engineer and engineering merchant, carried on by the said Reginald Bolton, at 110, Leadenhall-street, London, E.C.

ELECTRIC AND GENERAL CONTRACT CORPORATION (LIMITED).—The statutory return made up to March 31st has been filed. The nominal capital is £50,000, divided into 9,000 preference and 1,000 deferred shares of £5 each. The Company recently acquired the business of a contractor for electrical undertakings carried on by Mr. W. S. Graff Baker, at 35, Parliament-street, Westminster, S.W., including his rights in connection with electric tramways at Leeds, Coventry, and elsewhere. At the time of making up 805 preference and 1,000 deferred shares were taken up, and 799 deferred shares issued as fully paid. Upon the remaining 805 preference and 201 deferred shares, the full amounts have been called and £5,030 paid.

EDISON-BELL PHONOGRAPH CORPORATION (LIMITED).—The statutory return made up to April 6th has been filed. The nominal capital is £60,000 in £5 shares. At the time of making up all the shares had been taken up.

EDISON-GOWER-BELL TELEPHONE COMPANY OF EUROPE (LTD.).—The annual return was made up to and filed on April 14th, when 385,009 shares out of a total nominal capital of £500,000 in £1 shares were taken up; 370,000 of these were issued as fully paid, while the full amount has been called and paid on the remaining 15,009 shares.

ELIESON ACCUMULATOR (BRITISH PATENT) SYNDICATE (LIMITED).—The annual return made up to March 2nd has been filed. Out of a nominal capital of £12,000, in £1 shares, 2,007 shares have been taken up, and a call of 10s. per share made. The calls paid amount to £103. 10s., while those unpaid amount to no less than £900.

ELECTRICAL ADVERTISING SYNDICATE (LIMITED).—The annual return, made up to December 29th last, has been filed. 907 shares of £10 each, out of a capital of £10,000, have been taken up, the full amount called, and all calls (£9,070) paid.

ELECTRICAL PURIFICATION ASSOCIATION (LIMITED).—The annual return, made up to December 31st last, has been filed. 18,326 shares out of a nominal capital of £25,000 in £1 shares have been taken up, of which 5,000 have been issued as fully paid. Upon the remaining 13,326 shares the full amounts have been called, resulting in the payment of £13,226, and leaving £100 in arrears.

FAREHAM ELECTRIC LIGHT COMPANY (LIMITED).—The annual return, made up to March 30th, has been filed. The nominal capital is £5,000, in £1 shares, of which 4,158 have been taken up. Upon these the full amount has been called.

ELECTRICITY SUPPLY COMPANY FOR SPAIN (LIMITED).—The annual return, made up to January 12th, has been filed. The nominal capital of £100,000, divided into 19,900 ordinary and 100 founders' shares of £5 each, has been taken up, of which the founders' shares were issued as fully paid to Robert Hammond for registration and promotion expenses. Upon the 19,900 ordinary shares the full amount has been called and paid.

HASTINGS AND ST. LEONARD'S-ON-SEA ELECTRIC LIGHT COMPANY (LIMITED).—The annual return, made up to April 21st, has been filed. Out of a nominal capital of £50,000, in £10 shares, 1,667 shares have been taken up, the full amount per share called and paid.

WOODHOUSE AND RAWSON UNITED (LIMITED).—A petition was presented on April 25th by Mr. C. E. Challis for the compulsory winding up of this Company, and is down for hearing at the Royal Courts of Justice, London, on May 17th.

CITY NOTES, &c.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—Notice is given that the second drawing for payment of the Four per Cent. Mortgage Debentures of this Company, 106 in number, will take place on Monday, May 8th, at noon, at the offices of the Company, Winchester House, Old Broad-street, E.C.

CALLS DUE.—*May 5:* PRINTING, TELEGRAPH AND CONSTRUCTION COMPANY OF THE AGENCE HAVAS (LIMITED), £1 on 19,900 £5 shares. *May 15:* CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED), final £2 on 20,000 Accumulative Six per Cent. £10 preference shares; and ELECTRIC CONSTRUCTION CORPORATION (LIMITED), final £3 on 10,000 Six per Cent. Second Mortgage Debenture Bonds of £10.

CENTRAL AND SOUTH AMERICAN TELEGRAPH COMPANY.—The Board has declared a quarterly dividend of 1¾ per cent., after which there is a surplus of $51,772. This Company recently entered into a contract with the Government of Guatemala for a cable communication with that Republic, which it is expected will be completed in July. Guatemala will give a subsidy of $150,000 in gold to the new cable.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended April 23rd were £851, as against £807 for the corresponding period of last year, being an increase of £44. The total receipts for the half-year amount to £14,568 against £13,302 in the corresponding period of 1892, being an increase of £1,266.

MEXICAN TELEGRAPH COMPANY.—The Directors have declared a quarterly dividend of 2½ per cent., and report a surplus of $338,655 after the payment of dividend.

Hosted by Google

ST. JAMES'S AND PALL-MALL ELECTRIC LIGHT COMPANY (LIMITED).—It is notified that the electric current sold for the quarter ended March 25th last amounted to £10,119, as against £10,024 for the quarter ended March, 1892, a period of six days more.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended April 21, 1893, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,937.

Telephone 2714. Telegrams: "Electrician Newspaper London."

No. 780.—Vol. XXX. FRIDAY, APRIL 28, 1893.

Registered at the General Post Office.

SINGLE COPY ..... 4d.
POST FREE ..... 4½d.
Annual Subscription (U. K.), 19/6.

LATIMER CLARK, MUIRHEAD & Co.

REGENCY STREET, WESTMINSTER, LONDON, S.W. (LIMITED).

ELECTRICAL ENGINEERS & MANUFACTURERS.

APPLY DIRECT FOR Clark's Standard Cells (Dr. Muirhead's Patent Portable Form), Standard Condensers, Voltmeters, Ammeters AND ALL KINDS OF Electrical Measuring Instruments.

DYNAMOS and MOTORS (KAPP'S PATENT).

AS USED FOR:—
Central Stations,
Private Installations,
Factories,
Transmission of Power,
Ship Lighting,
Train Lighting,
Tramways,
Fan Driving,
Accumulator Charging,
Electro-Depositing,
Arc and Incandescent Lighting.
&c., &c., &c.

HIGH EFFICIENCY.
HIGH AND LOW SPEED.
GOOD WORKMANSHIP.
THOROUGHLY TESTED.
QUICK DELIVERY.
REDUCED PRICES.
Enquiries Invited.

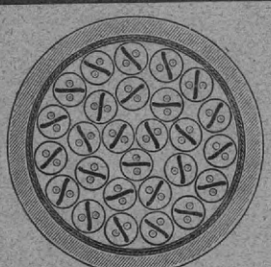
DYNAMOS, ALTERNATING AND CONTINUOUS CURRENT.

N.B.—Messrs. JOHNSON & PHILLIPS are the Owners of ALL Kapp's Patents.

Multipolar Machines as at St. Pancras Central Station. Large Alternators as at Paddington Central Station (Metropolitan Electric Supply Co.).

JOHNSON & PHILLIPS,

14, Union Court, Old Broad Street, London, E.C., & Charlton, Kent.



Patent Telephone Cable with Paper and Air Space Insulation.

FELTEN & GUILLEAUME, Mülheim-on-Rhine.

MANUFACTURERS OF

WIRE AND WIRE ROPES FOR ALL PURPOSES.

COPPER, COMPOUND, BRONZE, and PATENT DOUBLE BRONZE WIRES, TELEGRAPH, TELEPHONE and ELECTRIC LIGHT CABLES.

PATENT TELEPHONE CABLE with Paper & Air Space Insulation.

Capacity below 0,08 Microfarad per Stat. Mile.

100 PER CENT. CONDUCTIVITY. **COPPER WIRE** 100 PER CENT. CONDUCTIVITY.

Hard and Soft Drawn.

Copy of Report made by Prof. J. A. FLEMING, D.Sc., F.R.S.

"I have carefully examined and tested samples of Hard-drawn Copper Wire submitted to me by The Lancashire High Conductivity Wire Company. The Specific Gravity was very near 8·9. Its Electrical Conductivity is exceedingly near 101 per cent. reckoned by the usual Standard of Matthiessen. It was evident to me that it had been prepared from an excellent quality of Copper, and that it is well adapted both in its Hard-drawn and Annealed conditions for all Electrical Work.

(Signed) "J. A. FLEMING."

Sole Agents for the "NEVILE" AUTOMATIC ACCUMULATOR SWITCH.

This Switch balances the voltage of the cells against that of the dynamo, making and breaking the circuit when the one exceeds the other by more than 1 per cent.

They have been in use for many years, and should be fixed in every accumulator installation as a safeguard against the breaking of the belt or any other accident.

AS THE ACTION IS ABSOLUTELY RELIABLE THE NECESSITY FOR CONSTANT ATTENDANCE WHILE THE CELLS ARE BEING CHARGED IS OBVIATED BY THE USE OF THIS APPARATUS.

WHOLESALE AND EXPORT ONLY.

"SILENT" ENGINES (CHANDLERS' PATENTS)

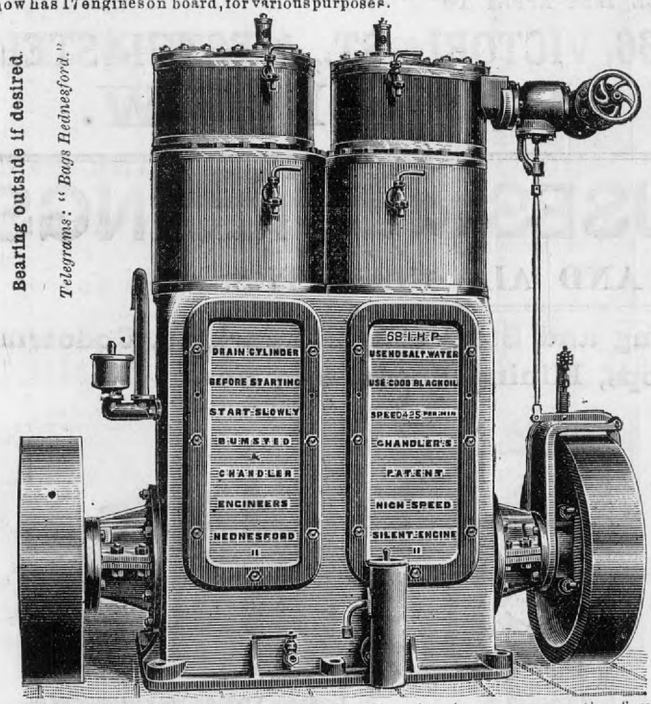
FOR ELECTRIC LIGHTING.

Made in **20** SIZES, with one or two cranks, from 2 to 200 Horse-power, **simple compound or tri-compound, giving the highest economy,** at speeds suitable for coupling direct to dynamos for THEATRE-LIGHTING, for CENTRAL STATIONS, for SHIP-LIGHTING, and TRAIN-LIGHTING.

Electrical Firms and Shipowners may place perfect confidence in these Engines, as they are the most durable ever introduced, and as economical as any other high-class engine. After prolonged and severe tests (which caused the engines of other makers to break down) these engines were selected for use on ss. "*Teutonic*"; these worked so satisfactorily that they were also selected for ss. "*Majestic.*" Each ship now has 17 engines on board, for various purposes.

Bearing outside if desired.

Telegrams: "Bays Hednesford."



One Electrical Firm has ordered no less than 40 engines in two years, another firm 32, another firm 19, another firm 16, another firm 14, and a large number of other firms have sent many repeat orders. Twenty of the British India Steam Navigation Company's Steamers are lighted by these Engines. All this goes to prove that the Engines are reliable and highly satisfactory. Many are working without lubrication to Cylinders. NO AIR NOR OIL CAN POSSIBLY PASS AWAY TO CONDENSER.

Every part can be got at comfortably when the door is removed.

Speed adjustable while Engine is running. Requires less care than any other Engine known, and uses less oil. **NO OIL IS LOST.** Engine easily understood. No complications Inside. Constructed to stand hard work. The Patent "Safety" Governors are Extremely Sensitive. They are mounted on the Crank Shaft and require no belt to drive them, and are everlasting.

Letter from Superintending Engineer of Sixteen Steamers with these Engines on board, says:—"*All the Engines are working very satisfactorily.*"

CHANDLER CROMPTON COMBINED COMPOUND PLANT.

For SHIP LIGHTING and TRAIN LIGHTING, as supplied to the Cape Government Railways and many Steamers.

ALSO

ACCLOMERATE BLOCK AND POROUS POT BATTERIES. LECLANCHE ACCLOMERATE BLOCKS OF ALL SIZES.

THE LECLANCHÉ-BARBIER CYLINDRICAL AGGLOMERATE WET CELL is the newest and most efficient form of Leclanché Battery. It is an open cell, all parts being instantly accessible, but so arranged as to render it practically a sealed one, with no evaporation or creeping salts.

No. 1.—E.M.F. 1·5 volts, I.R. 0·4 ohms. No. 2.—E.M.F. 1·5 volts, I.R. 0·8 ohms.

THE LECLANCHÉ-BARBIER CYLINDRICAL AGGLOMERATE DRY CELL possesses all the advantages of the wet one, with the special feature that not being sealed up (like all other dry batteries), any decrease in its E.M.F. can be at once restored by letting it absorb a little ammoniacal solution. The user can thus constantly maintain its efficiency at a trifling cost.

No. 1.—E M.E. 1·5 volts, I.R. 0·5 ohms. No. 2.—E.M.F. 1·5 volts, I.R. 0·6 ohms.

SOLE AGENT FOR GREAT BRITAIN AND THE COLONIES—

BOOKS FOR ELECTRICIANS, ELECTRICAL ENGINEERS, AND OTHERS.

The following Standard Electrical Works are sent post free to any address at the prices quoted :—

THE "ELECTRICIAN" SERIES.

IN TWO VOLUMES.

THE ALTERNATE CURRENT TRANSFORMER IN

THEORY AND PRACTICE. By J. A. FLEMING, M.A., D.Sc. (Lond.), Professor of Electrical Engineering in University College, London, &c., &c.

Vol. I., *500 pages, 157 illustrations. Third Issue, price 7s. 6d., post free (U.K.); abroad, 8s. 2d., post free.*

Synopsis of Contents.—Chapter I. Introductory.—Chapter II. Electro-Magnetic Induction.—Chapter III. The Theory of Simple Periodic Currents.—Chapter IV. Mutual and Self Induction.—Chapter V. Dynamical Theory of Current Induction.

Vol. II., *over 600 pages, and more than 300 illustrations. Price 12s. 6d., post free.*

Synopsis of Contents.—Chapter I. The Historical Development of the Induction Coil and Transformer.—Chapter II. Distribution of Electrical Energy by Transformers.—Chapter III. Alternate-Current Electric Stations.—Chapter IV. The Construction and Action of Transformers.—Chapter V. Further Practical Applications of Transformers.

370 pages, 159 illustrations, price 10s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER

METALS. By J. A. EWING, M.A., B.Sc., &c.

After an introductory chapter, which attempts to explain the fundamental ideas and the terminology, an account is given of the methods which are usually employed to measure the magnetic quality of metals. Examples are then quoted showing the results of such measurements for various specimens of iron, steel, nickel, and cobalt. A chapter on Magnetic Hysteresis follows, and then the distinctive features of induction by very weak and by very strong magnetic forces are separately described, with further description of experimental methods, and with additional numerical results. The influence of Temperature and the influence of Stress are next discussed. The conception of the Magnetic Circuit is then explained, and some account is given of experiments which are best elucidated by making use of this essentially modern method of treatment. The book concludes with a chapter on the Molecular Theory of Magnetic Induction; and the opportunity is taken to refer to a number of miscellaneous experimental facts, on which the molecular theory has an evident bearing.

The same book in German, price 8s. 6d., post free.

320 pages, 155 illustrations, price 6s. 6d., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS.

LAWS, UNITS, AND SIMPLE MEASURING INSTRUMENTS. By A. E. KENNELLY and H. D. WILKINSON, M.I.E.E.

Fully illustrated, price 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF

METALS. (Theoretical and Practical.) By Dr. GEORGE GORE, LL.D., F.R.S.

No other book entirely devoted to the Electrolytic Separation and Refining of Metals exists in any language; those on Electro-Metallurgy hitherto published being more or less solely devoted to electro-plating. The present book contains both the science and the art of the subject, *i.e.*, both the theoretical principles upon which the art is based, and the practical rules and details of technical application on a commercial scale, being thus suitable for both student and manufacturer.

Price 3s. 6d., post free.

THE STEAM-ENGINE INDICATOR AND INDI-

CATOR DIAGRAMS. Edited by W. W. BEAUMONT, M.I.C.E., M.I.M.E., &c.

A Practical Treatise on the Steam-Engine Indicator and Indicator Diagrams, with Notes on Steam Engine Performances, Expansion of Steam, Behaviour of Steam in Steam Engine Cylinders, and on Gas Engine Diagrams.

Second Edition, price 2s., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE, LL.D., F.R.S.

Price 2s. 6d., post free.

DIGEST OF THE LAW OF ELECTRIC LIGHTING.

By A. C. CURTIS HAYWARD, B.A., A.I.E.E. An abstract of the Electric Lighting Acts, 1882 and 1889, and of the various documents emanating from the Board of Trade dealing with electric lighting. The digest treats first of the manner in which persons desirous of supplying electricity must set to work, and then of their rights and obligations after obtaining Parliamentary powers; and gives in a succinct form information of great value to Local Authorities, Electric Light Contractors, &c. Revised up to January, 1893.

In Two Volumes—Price: stout paper covers, 2s., post free 2s. 2d. each; strong cloth, 2s. 6d., post free 2s. 9d. each. Single Primers, 3d., post free 3½d.

"THE ELECTRICIAN" PRIMERS. Fully illustrated.

A Series of Helpful Primers on Electrical Subjects.

TABLE OF CONTENTS:

Volume I.—THEORY.

Primer No.
1. The Effects of an Electric Current.
2. Conductors and Insulators.
3. Ohm's Law.
4. Primary Batteries.
5. Arrangements of Batteries.
6. Electrolysis.
7. Secondary Batteries.
8. Lines of Force.
9. Magnets.
10. Electrical Units.
11. The Galvanometer.
12. Electrical Measuring Instruments.
13. The Wheatstone Bridge.
14. The Electrometer.
15. The Induction Coil.
16. Alternating Currents.
17. The Leyden Jar.
18. Influence Machines.
19. Lightning Protectors.
20. Thermopiles.

Volume II.—PRACTICE.

Primer No.
21. The Electric Telegraph.
22. Automatic and Duplex Telegraphy.
23. The Laying and Repair of Submarine Cables.
24. Testing Submarine Cables.
25. The Telephone.
26. Dynamos.
27. Motors.
28. Transformers.
29. The Arc Lamp.
30. The Incandescent Lamp.
31. Underground Mains.
32. Electric Meters.
33. Electric Light Safety Devices.
34. Systems of Electric Distribution.
35. Electric Transmission of Energy.
36. Electric Traction.
37. Electro-Deposition.
38. Electric Welding.

The object of "The Electrician" Primers is to briefly describe in simple and correct language the present state of electrical knowledge. Each Primer is short and complete in itself, and is devoted to the elucidation of some special point or the description of some special application. Theoretical discussion is as far as possible avoided, the principal facts being stated and made clear by reference to the uses to which they have been put. Both volumes are suited to readers having little previous acquaintance with the subject. The matter is brought up to date, and the illustrations refer to instruments and machinery in actual use at the present time.

ADDITIONAL VOLUMES IN PREPARATION.

A POCKET BOOK OF ELECTRICAL ENGINEERING

FORMULÆ. By W. GEIPEL and H. KILGOUR. [*In preparation.*

With the extension of the heavier branches of Electrical Engineering the need of a publication of the Pocket-Book type dealing therewith increases; for while, on the one hand, there are many such referring to Mechanical Engineering, and, on the other hand, several which deal with Electrical Rules and Formulæ as more particularly applied to the lighter branches of Electrical Engineering, yet none of these alone suffice for the purposes of what may now be said to be the more numerous body of Electrical Engineering, viz.: those engaged in the application of Electricity to lighting, transmission of power, metallurgy and chemical manufacturing. It is to supply this want that this book has been prepared.

SUBMARINE CABLE-LAYING AND REPAIRING.

An Original Work on this important subject, which has not previously been treated in a thoroughly practical manner. By H. D. WILKINSON, M.I.E.E., &c., &c. Fully illustrated. [*In preparation.*

ELECTRO-MAGNETIC THEORY. By OLIVER HEAVISIDE.

[*In preparation.*

DRUM ARMATURE WINDING & COMMUTATORS:

IN THEORY AND PRACTICE. By F. M. WEYMOUTH. [*In preparation.*

A complete treatise of the theory, and the different methods of construction of Drum Winding, and also of close-coiled continuous-current Commutators, together with a full résumé of some of the principal points of consideration that are involved in their design.

ELECTRICITY AS A MOTIVE POWER. By ALBION

T. SNELL, Assoc.M.Inst.C.E., M.I.E.E. [*In preparation.*

INCANDESCENT LAMPS: Their Manufacture and

Use. By GILBERT S. RAM. [*In preparation.*

ELECTRIC LIGHT: ITS PRODUCTION AND USE. By J.

W. Urquhart. Fifth Edition, carefully revised, with large additions. Price 7s. 6d., post free (U.K.)

SITUATIONS VACANT AND WANTED, &c.

BOROUGH OF WOLVERHAMPTON.

ELECTRICAL ENGINEER.

The LIGHTING COMMITTEE appointed by the Town Council of Wolverhampton are about to put in force the powers conferred by the Wolverhampton Electric Lighting Order of 1890, and are prepared to receive APPLICATIONS for the APPOINTMENT of a resident ELECTRICAL ENGINEER whose duties will be defined by the Committee, and who must be competent to advise upon acceptance of tenders, to superintend the construction of all necessary works thereunder, and to undertake the supervision of the same when complete. One who has had actual practical experience in the working of some installation will be preferred. Salary, £300 per annum. Applications, accompanied by not more than three testimonials, endorsed "Electrical Engineer" to be sent to Mr. Horatio Brevitt, Town Clerk, Town Hall, Wolverhampton, by 6th May, 1893.

A PRINCIPAL is REQUIRED for the BATTERSEA POLYTECHNIC INSTITUTE. Candidates are requested to forward stamped addressed foolscap envelope for particulars to the SECRETARY, Battersea Polytechnic, 103, Borough-road, S.E.

ELECTRICAL ENGINEERING PUPIL.—The Electrical Engineer to the Corporation of Brighton has a VACANCY for an ARTICLED PUPIL at the Borough Electricity Works.—For terms, apply either to him or to Messrs. Lee, Ockerby and Everington, 114, Queen Victoria-street, E.C.

WANTED, in a moderate size Engineering Works in London constructing high-class electrical machinery, where practical and theoretical knowledge is necessary, a thoroughly well-trained ENGINEER, not over 30 years of age, with commercial knowledge, having natural energy and connection, and of gentlemanly address, as Assistant Manager. A good salary would be paid to a competent man. Capital not necessary, but applicants should be willing to invest a few thousands if found satisfactory.—Apply, stating past experience and salary expected, to Box 574, WILLING'S, 125, Strand, W.C.

WANTED, a capable ELECTRICAL ENGINEER, with fair connection, and about £2,000 capital, to join a well-established business in London. Principals only.—Apply, "A. L.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

WANTED a TRAVELLER with high references and good connections for the sale of incandescent lamps.—Address, 2249, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

WANTED at once, first-class WINDERS, accustomed to ring armatures.—State wages required and experience to No. 1893, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

ELECTRICIAN seeks ENGAGEMENT; 9 years with good firms. Central and Installation work; charge and supervision; home or abroad. Good testimonials.—Address, 1243, *Electrician* Office, Salisbury-court, E.C.

ELECTRICAL ENGINEER, used to responsibility of heavy work, desires putting down of complete plant or running station, home or abroad.—"Y. Z.," 71, Keppoch-street, Cardiff.

ELECTRICAL ENGINEER, with exceptional experience in Central Station and Construction work, seeks RE-ENGAGEMENT at home or abroad. Excellent references.—1249, *Electrician* Office, Salisbury-court, E.C.

ELECTRICAL ENGINEER (21) requires EMPLOYMENT as assistant; installation, central station, or office work. Technical and 2 years' practical training with a leading London firm. Testimonials.—Apply "X. Y.," 45, Norroy-road, Putney.

J. WEEKS AND CO., Horticultural Builders to Her Majesty, H.R.H. the Prince of Wales, H.M. Government, Admiralty Dept., War Dept., Royal Hort. Soc., Royal Botanic Soc., Parks and Public Buildings. Patentees of the Duplex Upright Tubular Boilers. King's-road, Chelsea, S.W.

Miscellaneous Advertisements, Plant Wanted and for Sale, &c., &c., continued on next page.

JUST PUBLISHED. WAISTCOAT-POCKET SIZE.

With Illustrations, 128 pages, 64mo, roan, gilt edges, 1s.; 1s. 1d. post free.

THOROUGH PRACTICAL ELECTRICIAN seeks RE-ENGAGEMENT as FOREMAN for all class of Installation and Central Station work; 13 years' experience in London, &c. Highest references.—Apply, H. EDWARDS 213, Cross-lane, Salford.

WANTED POSITION as RESIDENT ENGINEER or Assistant Manager of Electric Supply Station or Engineering Works by thoroughly practical man (25), experienced in laying down plant and machinery, also in management of men. First-rate references. Two years assistant engineer large Electric Lighting Co. Willing also to invest small capita'.—No. 1247, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

YOUNG MAN seeks SITUATION as WIREMAN, can do Electric Light, Telephone, and Bell Fitting; run own casing if necessary.—Apply H. ANGWIN, 6, Arwyn Cottages, Falmouth.

WANTED, and FOR SALE.

SPLENDID (clincher pneumatic) SAFETY BICYCLE, balls all over, with cyclometer, and all accessories complete. Cost about £17; new last August. Will exchange for good Wheatstone Bridge, complete, by good maker. —Apply, W. DURTNALL, Electrician, Cannon-street Hotel, London, E.C.

J. WEEKS AND CO., King's-road, Chelsea, S.W., supply all kinds of Boilers, their improved and other Valves, tested Hot-water Pipes, Castings, Connections and Fittings at lowest retail prices.

FOR SALE.—IN LIQUIDATION.

The BUSINESS, as a going concern, with the Machinery, Plant, Tools, Stock and Freehold, and all appurtenances thereto, together with the valuable patent rights used in connection with the business, of the AUTOMATIC STANDARD SCREW CO. (Limited), HALIFAX, in liquidation.

The Company is engaged in the manufacture of a very large variety of high-class screws for bicycle, electrical, telegraph, and philosophical instrument work, machine tools, and fancy turned metal.

For further information apply to the LIQUIDATOR, at the works.

MESSRS. DEBENHAM, TEWSON, FARMER, and BRIDGEWATER have a large selection of SHOWROOMS, OFFICES, WAREHOUSES, and FACTORIES suitable for ELECTRICAL ENGINEERS.

Their Monthly List is now ready, and may be obtained at their Offices, 80, CHEAPSIDE, E.C., or will be forwarded free by post

NEW CELLS FOR OLD.

It is frequently urged as an objection to the employment of Dry Primary Batteries that there is no means of recharging them; that when they become exhausted—which every Battery naturally must become sooner or later—they are useless and have to be thrown away. This objection does not apply to the

"E.C.C." DRY BATTERY

which when exhausted and returned in good mechanical condition to the

GENERAL ELECTRIC COMPANY,

69 & 71, QUEEN VICTORIA STREET, LONDON, E.C.,

is replaced by perfectly new cells, at half the original cost, which ensures to the user a saving of FIFTY PER CENT.

For statistics and opinions regarding this Battery write for Pamphlet, or see Prof. Jamieson's Lecture before the Glasgow Philosophical Society, March 22nd, 1893.

BARE COPPER MAINS

It has recently been stated in certain trade circulars that the "advantages claimed for systems of copper strip laid in culverts are mostly theoretical and disappear in actual work," and "that bare copper mains are inconvenient and unreliable, and expensive in first cost and subsequent maintenance."

THESE STATEMENTS ARE FALSE!!

And in respect of the Crompton "Strip" System of bare mains we can prove it, and that

The Advantages are Eminently Practical.
They do NOT Disappear in actual Work.
Bare Copper Mains laid on our System are the most Convenient for all purposes.
They have NEVER Failed. They Save in First Cost.
We Guarantee the Cost of Maintenance to be Less than that of any Insulated System.

We have never knowingly circulated false statements about other systems of insulated cables; we therefore claim unhesitatingly the right to publicly refute the above published statements which might be thought to apply to our bare strip system.

Shortest and Most Direct Route to India and the Far East,

BY SPECIAL WIRES.

DIRECT OVERLAND TELEGRAPHS

CONNECTED WITH

INDIA, BURMAH, PENANG, MALACCA, SINGAPORE, CHINA, MANILLA, COCHIN CHINA, JAPAN, JAVA, AUSTRALIA, NEW ZEALAND, PERSIA, SOUTHERN RUSSIA, TURKEY, AND THE EAST GENERALLY.

The greatest possible SPEED and ACCURACY in the Transmission of Messages are secured by the VERY LIMITED NUMBER of TRANSMITTING STATIONS on the LINE, by the use of INK-WRITING RECORDING INSTRUMENTS, by the employment of a Special Staff of Skilled ENGLISH TELEGRAPHISTS throughout the Line, and by a System of Control which is exercised over every Message.

Messages are accepted at the Company's Offices—

LONDON: 18, Old Broad Street, E.C., 6 and 8, Lime Street Square, and 10 and 11, Mincing Lane, E.C.

LIVERPOOL: Walmer Building, 6, Water Street.

MANCHESTER: 60, Spring Gardens.

Where receipts are given gratis for the charges made and whence messages are sent direct by Special Wire, and at any Postal Telegraph Office throughout the Kingdom.

ALL TELEGRAMS SHOULD BE MARKED "VIA INDO."

No Charge is made by any Telegraph Station for the transmission of the "Via."

Books of Forms and Tariff Books containing Rules and Regulations, Lists of Stations, &c., are forwarded post free on application to the Company's Head Offices, 18, Old Broad Street, London, E.C.

W. ANDREWS, *Managing Director.*

THE INDESTRUCTIBLE PAINT COMPANY, Ltd., 27, Cannon St., E.C.

BROWNING'S ENAMEL PAINT,

IN ANY COLOUR OR TINT.

READY MIXED. USEABLE AT ANY TIME. For **SHIPS, STEAMERS, YACHTS** (inside or outside), **LAMP-POSTS (Gas and Electric),** and for **ALL PURPOSES** where a hard and washable surface is essential.

THE INDESTRUCTIBLE PAINT resists the action of acids and alkalies. Invaluable for Iron Structures, Roofing, Gas Tanks, &c.

BROWNING'S COLOURLESS PRESERVATIVE SOLUTION is a perfect cure for Damp Walls. Makes Bricks, Porous Stone, Cement, &c., weatherproof. It was applied to **CLEOPATRA'S NEEDLE IN MAY, 1879,** and after eleven years' exposure to the trying climate of London, Mr. Dixon, C.E. (who brought the Obelisk to London), thus described the result in his letter to *The Times*, May 28th, 1890:—

"AFTER MAKING A CAREFUL PERSONAL EXAMINATION OF THE MONUMENT MY CRITICAL EYE FAILS TO DETECT UPON ITS SURFACE A SIGN OF ANY DECAY WHATEVER."

The Paints and the Solution secured the HIGHEST AWARDS at each of the Exhibitions—Fisheries, Health, and Inventions, in 1883, 1884, and 1885.

THE LEADING ATLANTIC CABLE CO.

SHORTEST MOST RELIABLE CABLE ROUTES

TO ALL PARTS OF THE AMERICAS.

DUPLEX—AUTOMATIC—SPEED.

The Entire System of this Company is Duplexed, making it equal to Four Single Cables. The "Commercial" merits the distinction of having reduced the time of transmission to a minimum, and of being the first to successfully introduce the Automatic System of working, a system which increases speed and decreases the chance of error to the lowest possible point.

In the matter of Quick and Reliable Service, Perfect Equipment and Connections, and completeness of every detail in its business, the "Commercial" occupies the foremost position.

CONNECTIONS.

POSTAL TELEGRAPH CO.—The greatest competitive system of Telegraphs ever maintained in the United States, covering all commercial points in the country.

CANADIAN PACIFIC TELEGRAPHS.—Reaching all important places in CANADA, from the Atlantic to the Pacific, and the only Company having lines in British Columbia.

"Via COMMERCIAL."

To insure your Cablegrams being forwarded by the ONLY INDEPENDENT Atlantic Cable Company, please mark them "Via Commercial," which indication is not charged for; or use this Company's own forms, bearing its GLOBE Trade Mark.

This Company's routes avoid all long land lines on both sides of the Atlantic.
